theaters were built for the citizenry, whereas those built outside the cities were intended to serve the pilgrims visiting the various worship compounds. Most of the urban theaters were erected without considering the city's street network—the site was generally selected for topographic reasons, for example, at Beth-Shean, Sepphoris, Sebaste, and Gadara. On the other hand, the North Theater at Gerasa is a fine example of a theater carefully integrated into the city's street network. In plan the theaters in the region are Roman and not Hellenistic. Hence, their orchestra is a semicircle rather than a circle and their seating, which partially rests on an artificial slope, does not extend beyond the orchestra semicircle. At the same time, almost all the region's theaters were erected on the slopes of hills in order to avoid having to build artificial slopes. Hence, in most instances, the lower seating complex *(ima cavea)* is set on a natural slope and the upper one *(summa cavea)* rests on an artificial slope. In keeping with the topography and constraints of a site, the upper sections of the cavea were erected in various ways. In most cases, they were sloped, radial, barrel-vaulted passages (vomitoria) that intersected with a semicircular corridor roofed by a continuous barrel vault (ambulacrum). Sometimes the *summa cavea* rests on an artificial sloped mound of earth supported by two semicircular monocentric parallel walls covered by a continuous barrel vault or the entire seating complex rests on an artificial slope of pressed earth supported by two semicircular monocentric parallel walls whose interior space is filled with earth.

As was customary in Roman theaters, stage structure *(scaena)* and seating complex *(cavea)* were turned into a unit by means of the *versurae,* or "wings." Typically there were three entrances in the stage's facade. The stage *(pulpitum)* extended to the foot of the *scaenae frons,* which was separated from the orchestra by the *proscaenium.*

The region's theaters were built of local stone and only the *scaenae frons* decorations, including its three-dimensional sculpture, were marble. The construction and original architectural solutions of the thirty theaters thus far discovered are outstanding. The largest theater in Syria-Palestine, at Philadelphia, could hold about seven thousand spectators; the smallest (Sahr in Trachonitis) held about four hundred. On the average, this region's theaters held about forty-five hundred people. Compared to theaters in Anatolia and North Africa, these are small. Yet, their construction, location, and distribution confirm the cities' ability to meet the considerable cost and engineering and architectural challenges entailed in erecting such complex installations. Most theaters continued to serve their original purpose until the latter days of the Byzantine period, which attests to their having truly expressed the cultural needs of most of the urban population in this region of the Roman world.

ARTHUR SEGAL

THUREAU-DANGIN, FRANÇOIS (1872–1944), French Assyriologist. Born in Paris, Thureau-Dangin joined staff of the Louvre museum in 1895, was nominated to the Académie des Inscriptions et Belles Lettres in 1917, and was curator of the Louvre's Near Eastern Antiquities Department from 1925 to 1928. His research constitutes the groundwork of what is currently known about the character of the cuneiform writing system and the deciphering of the Sumerian language. He published numerous Sumerian and Akkadian texts and interpretive monographs that still form the basis of scholarship on ancient Mesopotamian history, religion, and science.

A brilliant student of Jules Oppert (one of the pioneers of cuneiform decipherment), Thureau-Dangin was entrusted, in 1895, with studying the enormous quantity of literary, royal, and administrative inscriptions unearthed at the Mesopotamian site of Telloh by Ernest de Sarzec, who, by 1877, had established the existence of the Sumerians. Thureau-Dangin's first concern was to trace the evolution of cuneiform writing. In *Recherches sur l'origine de l'écriture cunéiforme* (Paris, 1898), he published a list of six hundred signs comprising their most recent and most ancient forms. His classification of signs, adopted by all Assyriologists and still in use, allows for a single mode of transcription for both Sumerian and Akkadian. This work led to two publications: *Le syllabaire accadien* (Paris, 1926), and *Les homophones sumériens* (Paris, 1929).

The publication of his book *Les inscriptions de Sumer et d'Akkad* (Paris, 1905) constituted a decisive step in the deciphering of the Sumerian language. In it he transcribed, translated, and established the grammatical rules of all the known royal inscriptions from the Archaic Sumerian era to the dynasty of Larsa at the start of the second millennium BCE. This seminal work, the first written synthesis of the Sumerian language, was immediately translated into German.

Thureau-Dangin enhanced the collection at the Louvre with numerous texts that were published, beginning in 1910, in a series entitled *Textes Cunéiformes du Louvre*. His autographs are unsurpassed. As good a historian as he was a philologist, he published the contents of the documents in his many articles, mainly in the *Revue d'Assyriologie et d'Archéologie Orientale*, of which he was coeditor.

Thureau-Dangin was also a field archaeologist. He conducted several surveys in 1924 at Tell Ashara (ancient Terqa), on the east bank of the Euphrates River. In 1927–1928 he excavated Tell Ahmar (ancient Til Barsip), on the west bank of the river, a mission that uncovered a ninth-century BCE provincial Assyrian palace. He simultaneously excavated at the neighboring site of Arslan Tash.

BEATRICE ANDRÉ-SALVINI

TIBERIAS, city located on the western shore of the Sea of Galilee, north of the hot springs known as Hammath Tiberias and bounded on the west by Mt. Berenice (200 m above sea level).

History. Named for the Roman emperor Tiberius, the city was founded in 20 CE during the reign of Herod Antipas, son of Herod the Great. In 61 CE the city was annexed to the kingdom of Agrippa II and remained a part of it until Agrippa's death in 96 CE. In 100 CE Tiberias came under Roman rule and, like the rest of the empire, began to prosper. It became a Roman colony in the reign of Emperor Elagabalus (218–222 CE). The institutions of Jewish leadership—first the Sanhedrin and then the patriarchate—both

were transferred from Sepphoris at this time, and Tiberias became the political and spiritual capital of the Jews. In the early third century, Rabbi Yohanan (d. 270), leader of the Sanhedrin, established the Great Beth Midrash ("academy"), possibly at the foot of Mt. Berenice. According to tradition, the greater part of the Jerusalem Talmud was codified there (see below).

The city's prosperity continued—and even improved—after the Muslim conquest in the seventh century. Tiberias became the capital of the Jund Urdun ("Jordan district"), whose boundaries roughly corresponded to those of the former Byzantine Palaestina Secunda (with its capital at Beth-Shean). Jews continued to constitute the majority of the population, followed by a sizable Christian community and a smaller number of Muslims. Tiberias was the capital of Galilee until the Crusaders captured it in 1099. The city was made the capital of the Galilee principality, which roughly corresponded to the Jund Urdun. The city wall was restored, and a large fortress was built to the north of the Roman-Byzantine city. The inhabitants then clustered around this fortress, from which the modern city of Tiberias would develop. In 1187, at the battle of Hattin, the city fell to Salah edh-Din (Saladin) and remained under Ayyubid rule until 1240, when the whole of Galilee once again came under Crusader control. Christian rule was short lived, however. In 1247 the city fell to Mamluk forces and remained under Muslim rule until the arrival of the British in 1917–1918.

Excavation Results. The first systematic excavation at Tiberias, of the southern gate and its environs, was conducted in 1973–1974 by the Israel Department of Antiquities and Museums, the Institute of Archaeology of the Hebrew University of Jerusalem, and the Israel Exploration Society, under the direction of Gideon Foerster. The gate, built in 20 CE, apparently marked the bounds of the city with a commemorative arch. When the Byzantine city wall was built in the sixth century, it was integrated into the gate, which then became part of the city's fortification system.

A long colonnaded street *(cardo)* that ran parallel to the Sea of Galilee extended north from the southern gate several hundred meters to the site's municipal area. In this area Bezalel Rabani, during the largest salvage excavation at the site under auspices of the Israel Department of Antiquities (1954–1956), uncovered the remains of the central *cardo* as well as the bathhouse and marketplace. The bathhouse abuts the *cardo* to the east. It is probably the bathhouse frequently mentioned in Talmudic sources. Built in the fourth century, it was used continuously until the city was destroyed in the eleventh century. Although its plan changed very little throughout this period, the structure itself underwent numerous alterations and restorations. Its length (east–west) was 42 m and its width (north–south), 31 m, for a total area of approximately 1,300 sq m. Some of the walls survived to a height of 2.5 m. North of the bathhouse and adjoining the *cardo,* Rabani uncovered three rows of column bases covering an area of more than 800 sq m. He dated these remains to the sixth century and interpreted them as a vaulted marketplace. At the eastern end of each two stood a huge square pillar, probably part of a tetrapylon, which had apparently

TIBERIAS. Figure 1. *General view of the basilical hall of the urban villa, looking east.* (Photograph by Sando Mondrein; courtesy Y. Hirschfeld)

TIBERIAS. Figure 2. *General view of the church atop Mt. Berenice, looking east.* (Photograph by Zev Radovan; courtesy Y. Hirschfeld)

supported an arch that spanned an adjoining street—the remains of similar pillars were found on the other side of the street.

About 80 m northeast of the bathhouse the remains of an urban villa complex (1,400 sq m) was cleared first by Adam Druks in 1964 and recently by Yizhar Hirschfeld (1993). The villa was built with a basilical hall and large courtyard according to symmetrical well planning (see figure 1). Two construction stages were discerned: the first dated to the fourth century CE, the second to the fifth–sixth centuries CE. The villa is situated in the center of the complex; it continued in use until the end of the Early Arab period.

In 1976 Fanny Vitto, on behalf of the Israel Department of Antiquities, uncovered a two-chambered, aboveground Roman tomb (8 × 10 m) in the Qiryat Shmuel neighborhood of the city. Numerous human skeletons were found in both chambers.

While leading a salvage expedition for the Israel Antiquities Authorities at the foot of Mt. Berenice in 1989–1990, Hirschfeld discovered a Roman (second–third centuries CE) theater to the west of the *cardo* about 130 m south of the baths. In 1990–1994 he excavated a 35-meter stretch of its wall built out of large basalt blocks that probably constituted its northeast corner. Preserved to a height of about 5.5 m, the wall helped support the spectator seats. A small portion of the stage, which faced north, also was uncovered. The theater's seating capacity has been estimated at about five thousand, comparable to that of the Roman theater uncovered at Beth-Shean. [*See* Beth-Shean.]

Also at the foot of Mt. Berenice, about 250 m from the shore, Hirschfeld excavated a Roman public building beneath the remains of private houses. This large (about 200 sq m) rectangular structure was built in the early third century CE and continued in use until the middle of the Byzantine period, during which it underwent few changes. The building's most impressive remnant was its mosaic pavement: a geometric design, devoid of human or animal images, with a white background decorated with three square black frames, each enclosing a series of triangular red frames. [*See* Mosaics.] A stepped bathing pool, possibly a

miqveh, or ritual bath, was uncovered on the east side of the pavement. [*See* Ritual Baths.] It has been conjectured that this building was the great academy where most of the Jerusalem Talmud was redacted. The neighboring caves in the cliffs of Mt. Berenice were referred to by Jewish scholars in antiquity as the caves of the Great Beth Midrash, substantiating the possibility.

From 1990 to 1992, while excavating on the summit of Mt. Berenice, Hirschfeld uncovered a church and monastery just inside the city wall (see figure 2). [*See* Churches.] According to Procopius the city-wall was constructed during the reign of Justinian in 527–565 (Procopius, *Buildings* 5.9.21). The site is on a peak overlooking the Sea of Galilee and was likely chosen because from it the area where Jesus conducted his Galilean ministry is visible.

The large basilical structure (48 m × 28 m), was built of basalt stones; its floors were paved in polychrome mosaics and fine marble tiles. Fronting the structure was a courtyard with a huge square cistern; three entranceways led from this courtyard to the church. A large central apse in the eastern wall was flanked by two smaller apses. Two rows of columns supported the roof, which probably was made of wooden beams and clay roof tiles. A smooth stone block with a hole (18 m in diameter) at its center was found underneath the altar in the central apse. The block resembles anchors found in and along the shore of the Sea of Galilee; however, its weight—nearly half a ton—is ten times that of the average ancient stone anchor. [*See* Anchors.] Considering its findspot, the stone may have had a religious significance, as in early Christianity the anchor was a symbol of security and hope (e.g., *Heb.* 6:19). Not long after this church was destroyed in the devastating earthquake of 749, it was rebuilt; the newer structure continued in use until the end of the thirteenth century.

The remains of one of the "thirteen synagogues" of Tiberias referred to in the Talmud was uncovered at the northern edge of the site in 1978–1979 by an excavation team led by Ariel Berman. The style of the mosaics in the floors indicates that the synagogue was built in the sixth century; it remained in use during Muslim rule in Palestine and was repaired after the earthquake of 749. In the twelfth century, when Tiberias was a Crusader city, a broad vault was built over it.

South of the city, at Hammath Tiberias, the site of hot springs famous for their healing qualities, two synagogues were uncovered during two seasons of excavations (1961–1963) conducted by the Israel Department of Antiquities under the direction of Moshe Dothan, assisted by Immanuel Dunayevsky and Shlomo Moskowitz.

YIZHAR HIRSCHFELD

TIGRIS. The Tigris River (Ar., Dijlah; Tk., Dicle; Akk., Adiglat; Sum., Adigima) originates in the southern slopes of the Taurus-Zagros mountains of eastern Anatolia, a range that rises to 2,000–2,500 m (6,600–8,200 ft.) above sea level, and separates the Tigris catchment from the Euphrates drainage and from the lake basins of Van and Urmia. The Tigris winds in a southeasterly direction through upland basins and narrow valleys of Turkey, where the river has a 1:500 average gradient as it drops from Ergani (1,000 m [3,300 ft.]) to Cizre (350 m [1,150 ft.]). Once in Iraq, the river moves through a rolling piedmont plain and drops with a gentler 1:1,500 gradient, passing Mosul at 210 m [690 ft.] In northern Iraq, the river cuts deeply into the surrounding plain, forming a narrow alluvial zone bounded by cliffs and hills. South of Samarra (65 m [210 ft.]), the river enters the extensive Mesopotamian alluvial plain, where it forms first a meandering single channel and then a braided channel shortly before joining the Euphrates River to form the Shatt al-Arab and emptying into the Persian Gulf. In this section, the river has the extremely low gradient of 1:15,000 south of Baghdad and 1:30,000 as it approaches the Shatt al-Arab. Along its approximately 1,900 km (1,200 mi.) length, the river receives water from left-bank tributaries that drain different sections of the Taurus-Zagros ranges. The most important of these tributaries are the Batman Su and the Bohtan Su in Turkey, and the Upper Zab, the Lower Zab, the Adhaim, and the Diyala in Iraq.

The flow of water through the Tigris system is extremely variable through the year, in response to the predominantly winter rainfall and spring meltwaters in the uplands. The average peak flow occurs in March, April, and May, the flow in the different subdrainages peaking at slightly different times (the Lower Zab and the Diyala peaking in March, the Upper Zab in May, and the Tigris north of Mosul in April). The flow is also extremely variable from year to year, modern records at Mosul showing annual averages ranging from about 200 cu m/sec. (7,000 cu. ft./sec.) to 900 cu m/sec. (32,000 cu. ft./sec.). Moreover, locally heavy winter rains in the Taurus and Zagros make the river subject to disastrous flooding, and living and farming on the Tigris floodplain is notoriously risky.

The winter rainfall is adequate in amount and regularity for dry farming along the northern sections of the Tigris, down to the confluence of the Upper Zab, and in the upper

reaches of all its major tributaries. But south of the Upper Zab, the Tigris flows through areas in which dry farming is unreliable or impossible, although the average rainfall does support pasture land east of the Tigris and south of the Upper Zab, making this Transtigridian area important for animal herding. Unlike the Euphrates, the Tigris is ill suited to irrigation because of its tendency to destructive floods and to its deeper incision into the alluvial plain. Accordingly, population traditionally has concentrated in the piedmont zone of northeastern Iraq (dry farming) and along the Euphrates River (irrigation). Farther north in the Taurus-Zagros foothills, arable land, not rainfall, is the limiting factor, and cities like Diyarbakır occur only in the larger plains of the upper Tigris drainage. The higher rainfall does maintain lush pasturage and forest cover, and animal herding is an important component to economic life.

The Tigris drainage offered several additional attractions. The Diyala penetrates the western folds of the Zagros Mountains and ultimately gives access to the Iranian plateau and the Khorassan road that runs toward Central Asia. Other routes lead to the Van and Urmia basins, mountain valleys farther north, and ultimately to the Iranian plateau. The Tigris itself offers access to eastern Anatolia and a direct route to the rich Malatya, Elazig, and Mus plains of the Euphrates drainage. Rich sources of copper occur in the Taurus range at the headwaters of the Tigris, the Ergani-Maden area being only the best known; silver and other metals also exist. The uplands also contain various useful rocks, like limestone for building and flint for chipped stone tools. Furthermore, bitumen seeps exist in many places between the Tigris and the Taurus-Zagros high country.

Archaeological investigation of piedmont and mountain basins in the Tigris drainage has revealed a long succession of prehistoric cultures. Shanidar Cave, near the Upper Zab, contains Neanderthal burials in Middle Palaeolithic levels, and the other Paleolithic and Epipaleolithic sites also lie in the Zagros valleys. The Taurus-Zagros foothills are an important part of Robert Braidwood's "hilly flanks" hypothesis about the beginnings of food production, and important pre-pottery and ceramic Neolithic sites occur in this zone (e.g., the aceramic sites of Hallan Çemi and Çayönü, with permanent architecture and early use of copper).

The middle Tigris area was home to several late Neolithic and early Chalcolithic cultures, characterized by a succession of incised and painted pottery styles during the sixth and fifth millennia BCE. The Hassuna and Halaf cultures flourished in the piedmont zone where dry farming was the basis of life, and farther south the Samarran and Ubaid cultures relied on irrigation. The Halaf culture achieved an enormous distribution along the southern fringe of the Taurus Mountains, and is present through the upper Tigris drainage and into the Lake Van basin. During the fifth millennium, the Ubaid style of pottery replaced the Halaf styles in the north, as reflected in the archaeological sequences at Tepe Gawra and elsewhere in the middle Tigris drainage.

The settlement history of southern Mesopotamia expresses the disadvantages of the Tigris for settled, agricultural life. The cities of Sumer and Akkad relied mainly, if not exclusively, on the Euphrates River system for irrigation, and the principal southern Mesopotamian cities were located on the Euphrates channels. The Diyala River, on the other hand, supported cities like Eshnunna (Tell Asmar), Tutub (Khafajeh), Ishchali, and others, the excavations at which have provided rich archaeological and textual information about early Babylonia. Moreover, the northern edge of the alluvium and the Transtigridian areas were important for animal husbandry. During Kassite and Isin II times, for example, the Transtigridian area held tribal groups, often only nominally under state authority, whose social structure was based on extended families (lineages). Similarly, the Arameans who started arriving during the eleventh century most commonly inhabited the Tigris portions of the Babylonian alluvium, and maintained a kinship-based social organization.

The secondary role of the Tigris changed late in the first millennium. The Macedonian Greeks founded a capital city at Seleucia on the right bank of the river. The Parthians and Sassanians moved the capital across the river to Ctesiphon, a site most famous for the enormous arch that survives from a palace of Khusrau I. The ʿAbbasid caliph al-Mansur founded Baghdad in the 760s, and the later caliphs al-Muʿtasim and al-Muʿtawakkil built an enormous city at Samarra during the ninth century CE. These places enjoyed access to surrounding regions in all directions: by canal to the Euphrates and Syria, the Tigris into eastern Anatolia, the Diyala onto the Iranian plateau and Central Asia, and down the Tigris to the Persian Gulf. Use of the Tigris for irrigation expanded during the same periods, as the Seleucids increasingly tapped into the Tigris, and the Parthians constructed increasingly complex irrigation systems. These developments reached a peak with the construction of the Nahrawan irrigation system, the main feeder of which left the Tigris in the area of Samarra, crossed and absorbed both the Adhaim and the Diyala, and watered fields east of the Tigris. The civil strife and the Mongol invasion led to the decline of these cities and the regional irrigation works.

Cities appeared in northern Mesopotamia by the mid-third millennium BCE, exemplified by Tell Taya in the Jebel Sinjar region and other urban areas in the Khabur drainage farther west. On the Tigris, the early phases of the Ishtar Temple at Aššur (Qalʿat Sherqat) belong to this period, and Nineveh had been occupied since Hassuna times. The creation of cities and their wealth in the dry-farming zone laid the foundation for Assyria's subsequent imperial history, both as the prize of other kingdoms, and as the source of the Middle Assyrian and Neo-Assyrian empires. The geography of northern Mesopotamia also contributed to this

role, by offering trade routes. Indeed, the Cappadocian trade of the early second millennium, when Assyrian mercantile communities lived in Anatolian cities, is the best known period of Aššur's early history.

Although Aššur (associated with the national god of the same name) and Nineveh were the traditional centers of Assyria, Middle Assyrian, and Neo-Assyrian kings repeatedly established new royal cities. The new foundations included Kar Tukulti-Ninurta, just upstream from Aššur, but the greatest concentration of Assyrian cities lay in the dry-farming area north of the Upper Zab and east of the Tigris. These places, including Nimrud (Kalḫu), Kar-Shalmaneser, Khorsabad (Dur Sharrukin), and Balawat (Imgur-Bel), have provided the best-known examples of Assyrian art and culture, including palace and temple architecture, wall reliefs, and enormous apotropaic (protective) winged-bull figures, obelisks and altars, the Nimrud ivories, the Balawat bronze-door reliefs, and the libraries of Sennacherib and Ashurbanipal.

The Semitic-speaking Assyrians were not the only linguistic or ethnic community to occupy the middle Tigris during historic times. The Hurrians, known primarily by their personal and place names, first appeared during the third millennium, when they were most common east of the Tigris and in the Khabur area. By the mid-second millennium, Hurrians had spread across large areas of Syro-Palestine, forming local dynasties and then the Mitanni federation, centered on the Khabur triangle, that subordinated Aššur and played a key role in fourteenth-century BCE international politics. At this time Arrapha (modern Kirkuk) and Nuzi, both in the upper Adhaim drainage, were important Mitanni centers. The Mitanni federation fell apart in the fourteenth century, under the pressure of a resurgent Assyrian state.

The smaller plains and valleys of the upper Tigris offer less scope for urban growth and powerful states. The archaeological evidence indicates that the upper Tigris drainage contained relatively few Bronze Age settlements (the nature of which are poorly known) but that Iron Age sites are more common. The Middle and Neo-Assyrian royal inscriptions provide the basic knowledge of the petty kingdoms and tribal chiefdoms that occupied the small plains in upper Tigris and Upper Zab drainages. Hurrians continued to rule petty kingdoms in the upper Tigris hill country after the Mitanni collapse. Middle Assyrian kings campaigned against the forty kings of Na'iri, Musri, and Uruatri, in the region between the upper Tigris drainage and Lakes Van and Urmia, and against the Hurrian kingdoms (Shubari lands) along the Tigris itself; for a brief time during the thirteenth-century Assyria controlled much of the upper Tigris (Katmuhki). The ninth-century Assyrian kings campaigned regularly in the upper Tigris, including Musasir (with its shrines to the Hurrian gods Teišeba and Khaldi, in the upper Great Zab), Amed, and Katmukhi, briefly establishing a Nairi province. Several Assyrian kings left reliefs and inscriptions at the source of the Tigris, to commemorate their passage through the region.

New groups like the Muški, probably speaking an Indo-European language and related to the Phrygians, began arriving in the eastern Anatolian uplands in the twelfth century BCE and moved into the upper Tigris from where they briefly threatened Assyria. An Aramean dynasty (Bit-Zamani) came to rule Amed (the classical Amida, modern Diyarbakır) by the tenth century, and Arameans were strongly present in the Shubari and Katmukhi districts of the upper Tigris drainage. However, the major development was the emergence, despite the obstacles of geography, of the Urartian state from the multitude of petty Hurrian kingdoms during the first centuries of the first millennium BCE. The Urartians soon expanded their control over neighboring regions in the ninth and eighth centuries, and by the early eighth century they confronted Assyria around the upper Tigris. Both Assyria and Urartu disappeared during the rapid changes of the mid-first millennium, with Cimmerian and Scythian incursions and the rise to regional domination by the Neo-Babylonians and Medes, soon followed by the world empires of the Achaemenids, Seleucids, Romans, Parthians, Sasanians, and Byzantines. The upper Tigris remained a pivotal zone of imperial confrontation, as illustrated by the bloody history of Amida.

CHRISTOPHER EDENS

TIL BARSIP, impressive ancient site of Tell Ahmar, Syria, located on the east bank of the Euphrates River, about 20 km (12 mi.) south of modern Jerablus (a large town 3 km, or 2 mi., south of the ancient city of Carchemish on the other side of the Syrian-Turkish border), about 100 km (62 mi.) northeast of Aleppo, and 140 km (87 mi.) north of Tabqa, roughly following the Euphrates, where the dam that creates Lake Assad is located (36°39′ N, 38°07′ E). Tell Ahmar was the location of Til Barsip, the capital city of the Aramean kingdom of Bit-Adini, possibly called Masuwari as a Hittite city (Hawkins, 1983). [*See* Arameans; Hittites.] It was renamed Kar-Shalmaneser immediately after its conquest by Shalmaneser III in 856 BCE. A French expedition directed by François Thureau-Dangin excavated the site in three seasons (1929–1931) after initial soundings in 1928. Thureau-Dangin published the results in 1936. A salvage project there has been directed by Guy Bunnens of the University of Melbourne since 1988, following a survey of the site and surrounding area in 1987.

The site is situated at the edge of a terrace overlooking the alluvial plain of the Euphrates, about 1.5 km upstream from the confluence with the Sajur River. It is configured into three distinct areas: the acropolis (250 × 150 m) which originally stood 25 m above the surrounding plain; a second section extending 350 m to the west of the acropolis that is 10–15 m higher than the surrounding plain; and a very large semicircle (diameter, 1,200 m) centered on the acropolis that marks the third area and barely rises above the level of the surrounding plain. Excavation has documented the following periods of occupation: Ubaid, Early Bronze, Iron Age I and II, Persian, Hellenistic, Islamic, and modern.

The best-known material from the early sequence at Tell Ahmar comes from the hypogeum tomb excavated by Thureau-Dangin (Thureau-Dangin and Dunand, 1936, pp. 96–119). This rich assemblage of 1,045 complete vessels includes cups, chalices, a variety of plain bowls, chalice bowls, tripod bowls and jars, plain jars, "teapots," and a variety of exotic vessels in common wares and metallic wares with variants in black and with delicate red-line decoration. Bronze tools and weapons include shaft-hole axes, daggers, pins, spearpoints, and a decorated rein guide. This tomb group has for decades been a primary point of comparison in the middle of the third millennium for the archaeological assemblage of northwestern Syria. Recent salvage excavations along the Euphrates now place it in a broader EB context with an abundance of material from places like Tell Halawa (Orthmann, 1981) and Tell Hadidi (Dornemann, 1988) to the south and Jerablus/Tahtani (Peltenburg, 1994), Kurban Höyük (Algaze, 1990), and Noršuntepe (Hauptmann, 1982) to the north. [*See* Grave Goods.]

Only sherds indicate earlier occupation in the Ubaid and possibly Uruk periods, but a larger ceramic corpus from the beginning of the Bronze Age (early third millennium) is now available and is best represented by reserved slip wares (Bunnens, 1990, pp. 25–44, 46–99).

There seems to be a break in the occupation sequence until an Aramaic or Neo-Hittite occupation is established on the acropolis in Iron Age I. Little is published of the Iron Age pottery, but several large, possibly palatial buildings were excavated in an area more than 70 × 55 m on the acropolis. It is still unclear whether this complex is in some way associated with Aḫuni, the ruler of Bit-Adini mentioned by Shalmaneser III in an 858 BCE inscription. Luwian inscriptions in Hittite hieroglyphic script, probably dating primarily to the ninth century BCE, were found on the second level of the tell, on the west. [*See* Luwians.]

After the conquest of Til Barship by Shalmaneser III, an Assyrian palace covered the entire area of the acropolis. [*See* Palace.] More than 132 × 88 m was excavated; the building originally was larger, but had been eroded away. The palace was very elaborate, with stone door sockets and sills, floors paved with burned bricks and complex pebble mosaics, and a well-constructed drainage system. It was also decorated throughout with murals. [*See* Wall Paintings.] Excellent examples of Assyrian art are preserved here in multicolor decoration that adds a unique aspect to an otherwise limited color palette for the art of the period. In addition to a large variety of standard Assyrian geometric decorations are extended scenes of the Assyrian king hunting lions, holding audiences, and receiving tribute; processions with horses, chariots, soldiers, and prisoners; scenes of executions; representations of fish men, bull men, and genii; and scenes of rituals. All of these are well known from the palace reliefs at

Nineveh, Khorsabad, and Nimrud. [*See* Nineveh; Khorsabad; Nimrud.]

Assyrian occupation continued through the Neo-Assyrian period (to 612 BCE) and covered the lower tell as well as the acropolis. One of the gates of the defensive wall that ran along the edge of the lower tell was excavated. The gate was decorated with monumental lion orthostats. The inscription on the lions identifies them as dedications by the *tartân* (Assyrian military governor) Shamshi-Ilu, who apparently served Shalmaneser IV, Ashur-dan III, and Ashurnirari VI during the first half of the eighth century BCE. A number of other Assyrian inscriptions were found on the lower tell, including two stelae of Esarhaddon (680–669 BCE) and a stela dedicated to the goddess Ishtar. Many fragments decorated in relief in Assyrian and local art styles were also recovered.

Recent excavations have contributed a rich collection of objects from large private dwellings in several areas on the lower tell (Bunnens, 1993–1994). Black-and-white pebble mosaics were used as flooring in several of these buildings. One building shows remains of decorated wall plaster and another yielded a fragment of a cuneiform tablet. [*See* Cuneiform.] Cylinder and scarab seals, decorated ivories, bronze fibulae, armor scales, horse trappings, and an iron dagger and iron blades were among the many objects found. [*See* Seals; Jewelry; Weapons and Warfare.] Thin palace ware and fine gray and red-slipped wares are represented among the large quantities of pottery excavated.

The later occupations at Tell Ahmar were not extensive. There are remains of Persian-period tombs with typical grave goods, including scarabs, bronze bowls decorated in repoussé, bronze bracelets, and other bronze vessels. The Hellenistic occupation was the most extensive of the later occupations but was still very limited. Dressed stones were found in this level that may have been part of the socle belonging to a small sanctuary. Coins of Antiochus VII, Demetrius II, Antiochus VIII, and Antiochus IX bracket a period between about 138 and 95 BCE for this occupation. A selection of typical Hellenistic mold-made figurines was also associated with this level. Very little of the site's Islamic and modern remains has been published.

TILE. [*This entry comprises two articles:* Building Tile *and* Decorative Tile.]

Building Tile

Baked clay roof tiles were invented in Greece in the first half of the seventh century BCE. At first simply a means of waterproofing a roof, tiles soon became vehicles for decoration, and as such were a distinctive characteristic of Archaic Greek architecture, primarily on temples. The technology and taste for tiles spread over much of the Mediterranean in the second half of the seventh century, reaching Anatolia by about 600 BCE. The tradition there, flourishing for the next hundred years, was characterized by elaborate, often figural decoration, the use of relief-molded friezes, and the application of tiles to both sacral and nonsacral architecture.

Evidence for Anatolian tiles is concentrated in western coastal areas (e.g., at Miletus and Didyma in Ionia; Neandria and Larissa in Aeolis). [*See* Miletus.] Ionian colonization in the Black Sea area brought tiles to Sinope and Akalan on the Pontic coast. Overland trade routes funneled the technology to inland sites (e.g., Sardis on the Hermus River; Gordion on the plateau). [*See* Sardis; Gordion.] The exact mode of transport is uncertain, although itinerant coroplasts equipped with tools, molds, and pattern books are likely. Tiles have not been found farther east than Boğazköy and Pazarlı, within the bend of the Halys River. [*See* Boğazköy.]

The principal roofing system in Anatolia was a hybridization of the Greek Corinthian and Laconian styles, combining flat pan tiles with rounded cover tiles. The regular Corinthian style was also used. Roofs were often bichro-

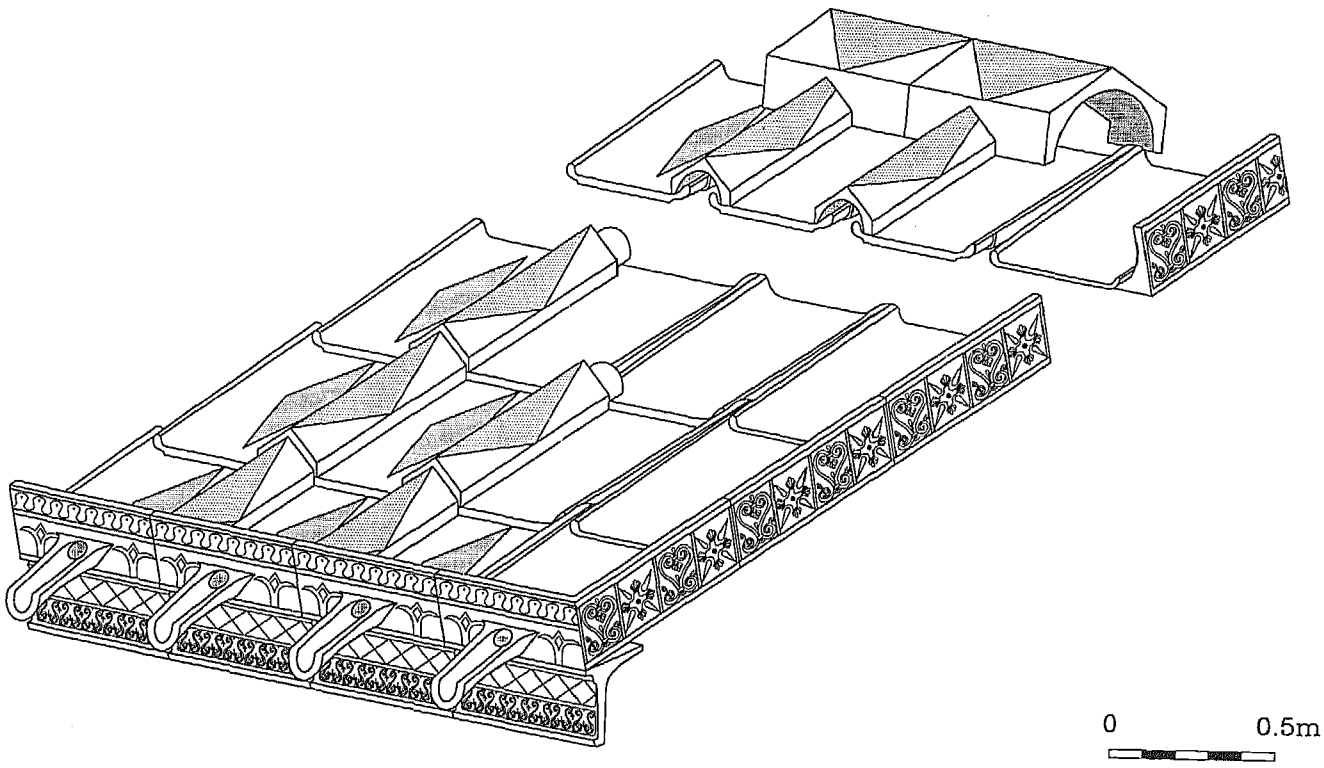
matic—the individual tiles slipped black, white, or red. Some tiles carried more elaborate decoration: a large lozenge at Miletus, Sardis, and Gordion (see figure 1); chevrons at Sardis. A predilection for patterned roofs characterized the Anatolian tradition. The method of draining water over the eaves, as well as the sorts of decoration applied at the roof's edge, varied from region to region.

Southern Ionian coroplasts adhered largely to mainland Greek practice, employing simple eaves tiles and antefixes. A characteristic roof, datable to the third quarter of the sixth century BCE, was recovered in a temenos along the Sacred Way between Miletus and Didyma. The eaves tiles are decorated in relief with a guilloche, the pentagonal antefixes with a gorgoneion. Lotus blossoms or lion protomes decorate antefixes at neighboring sites. Also typically Greek is the use of a raking sima (a vertical gutter along the raking eaves of a double-pitched roof). One example from Didyma is painted with the so-called Doric leaf pattern, in close imitation of Greek types from the second quarter of the sixth century. [*See* Didyma.]

Coroplasts in northern Ionia, Aeolis, and Lydia made use of the lateral sima (a tall gutter pierced by spouts along the horizontal eaves). Such simas were rare in Archaic Greece but were a defining feature in these regions. Raking simas were also employed. Both types of gutter were richly decorated in relief with motifs inspired from the repertoire of Greek metalwork and pottery painting. Figural scenes such as chariot racing were prominent, as were Greek egg-and-dart moldings. Tile types such as the disk acroterion show influence from Greek Laconia.

Lateral and raking simas were also used inland at Akalan, Düver, and Gordion. More typical of the region, though, as at Düver, Gordion, and Pazarlı, was a type of roof that employed spouted eaves tiles and antefixes that clamped over their front edge. In contrast to western Anatolian practice, antefixes and raking simas at inland sites frequently carried geometric patterns such as checkerboards, lozenges, or frets—ornaments derived from the traditional Phrygian decorative vocabulary. There is an intriguing similarity between Phrygian tiles and the decoration of rock-cut facade monuments in the Phrygian highlands, although the relationship between the two media remains unclear.

The hallmark of the Anatolian tile tradition was the decorative frieze, made up of revetment plaques molded in relief and brilliantly painted. Such friezes sheathed the horizontal and raking geison, or wooden beams in half-timbered constructions. At western sites, decorative motifs take on an obviously Greek flavor—either abstract, such as the lotus and palmette, or figural, such as Herakles battling centaurs. Inland, at Düver, a series of revetments decorated with a horseman and griffin displays a more "Anatolian" style. On the plateau, at Gordion and Pazarlı, motifs have a distinctly Near Eastern bias: bow hunting from a chariot or heraldic lions, bulls, and goats. The taste for decorative friezes may



TILE: Building Tile. Figure 1. *Reconstructed roof, Gordion.* (Courtesy M. R. Glendinning)

have derived from the Near East, as represented by Assyrian or Syro-Hittite relief sculpture, although the exact mechanism and extent of such influence is in question. [*See* Assyrians; Hittites.] The tile friezes possibly bore some relationship to the genesis of the Greek Ionic frieze, although the former were no more than repetitive bands of decoration and were never narrative.

In Anatolia the tradition of using decorated roof tiles peaked during the second and third quarters of the sixth century BCE. Although tiles remained in use throughout the rest of antiquity and into the Byzantine era, later examples were greatly simplified and far less decorated. Finds such as a public tile standard at Assos suggest that economical, standardized production became more important than ornamentation. Hellenistic and Roman roofs (e.g., at Assos, Priene, Sardis, and Gordion) consist of flat pans and pitched or rounded covers, with decoration limited to the antefixes (e.g., palmette and scrolls), the front edge of the eaves tiles (e.g., meander), or an occasional lateral sima (e.g., tendrils and palmettes). In Byzantine times expedient use was made of identical curved tiles for both the pan and cover elements. A separate architectural tradition in the Roman and Byzantine periods involved the use of tiles (bricks, essentially) to form decorative patterns of masonry.

Ramage, Andrew. *Lydian Houses and Architectural Terracottas*. Cambridge, Mass., 1978. Catalog of representative tiles recovered by American excavations since 1958. The proposed chronology, based on inadequately documented stratigraphic evidence, should be used cautiously.

Ratté, Christopher. "Archaic Architectural Terracottas from Sector ByzFort at Sardis." *Hesperia* 63 (1994): 361–390. Catalog and discussion of tiles recovered in the 1980s at Sardis, with stratigraphic evidence for dates.

Winter, Nancy A. *Greek Architectural Terracottas from the Prehistoric to the End of the Archaic Period*. Oxford, 1993. The most up-to-date survey of Greek terracottas, including a section on Anatolia. Many sound emendations to Åkerström's chronology are suggested.

MATTHEW R. GLENDINNING

Decorative Tile

The art of tile production for architectural decoration, which flourished in Mesopotamia and Achaemenid Iran during the first millennium BCE and persisted through the Parthian period, seemingly ceased in the seventh century CE with the Sasanian Empire of Persia. It was revived in the Islamic Empire of ʿAbbasid Iraq in the ninth century CE and spread rapidly throughout the Islamic world: technical perfection was achieved in the later imperial tradition of Spain, Morocco, Iran, and Turkey. While Byzantium incorporated some of the utilitarian ceramic ware and decorative vocabulary developed by the ʿAbbasids and succeeding Muslim dynasties, tiles for wall decoration were never a favored medium in the non-Islamic Near East.

The monumental architecture of the Assyrian capital of Babylon under Nebudchadrezzar II (604–562 BCE) exemplifies the mastery of the art of tile production for architectural decoration. Sixty mighty lions measuring three meters high with glazed yellow or red manes are cast in relief and set in a blue glazed ground and appear along the processional way leading to the Ishtar Gate. The Ishtar Gate, the 10.5-meter-high double gate that affords entry to the massive royal palace and urban complex of the Assyrian capital and holy city, dated to 580 BCE, also includes these regal lions greeting and impressing visitors to Babylon. Dragons symbolizing the generative force of new life, and bulls, serving as the chief of the gods, appear in alternating rows on the walls of the south palace complex. In all, 575 animals adorned the palace walls and massive entrance gate, 152 of which survive. Each glazed brick was produced as a unit and fitted later into the composition and formed the facing of the mud-brick construction of the city. City walls were covered with yellow, palaces with red, and temples with white glazed bricks, a gleaming urban polychromy declaring the power of the Assyrians. [*See* Assyrians; Babylon.]

After the Persian conquest of Babylon in 539 BCE, the Persian Achaemenid capital of Susa at Elam inherited the glazed tile tradition of Babylonian fame. Glazed gryphons, bulls, archers of the royal bodyguard, and large rosettes are the typical iconographic motifs proclaiming the Babylonian conquest and Achaemenid dominion from the walls of Susa. While ceramic production continued through the Parthian and Sasanian periods, tiles are not the favored medium for wall decoration again until the early Islamic period. [*See* Persians; Susa.]

The earliest surviving examples of ʿAbbasid wall tiles are located in the mid-ninth-century architecture of the ʿAbbasid capital at Samarra, Iraq. [*See* Samarra, *article on* Islamic Period.] The technique is metallic luster, an Islamic innovation in the eighth century, in which a metallic pigment is applied in patterns over a white tin glaze and then fired a second time in a reducing atmosphere. The original intent of using luster was to imitate the forms and designs of the more prestigious art of metalwork. After 850 CE, luster was

first used in wall tiles for architectural decoration, with the center of the industry in Baghdad. [*See* Baghdad.] The slightly later (860 CE) incorporation of 150 luster tiles stylistically similar to the Samarra tiles as part of the *miḥrab* (prayer niche) decoration of the Great Mosque of Kairouan (Qayrawan, in present-day Tunisia) indicates that the method of production and usage had spread extensively in the Islamic world of the period. Some of the tiles were brought from Baghdad and others made on site by a craftsman from Baghdad, suggesting that there were itinerant craftsmen moving from site to site.

Iran, Twelfth–Thirteenth Century. From 1100 CE in Iran, the principles of polychrome tile production evolved slowly, culminating, at the beginning of the thirteenth century, in a grand tradition of wall decoration that altered the course and the aesthetics of Iranian architecture. Colorful tiles covered large expanses of the sand-colored walls of buildings, focusing attention on the decoration of both the exterior and interior of monumental architecture, including private mansions, mosques and mausolea. [*See* Mosque; Mausoleum.] The type of building dictated the decorative repertoire. For example, religious buildings excluded figural motifs, favoring the Word of the Qur'an, and floral and geometric motifs. The palaces, unrestricted by the avoidance in Islam of figural imagery in religious buildings, freely explored princely leisurely iconography, such as narrative depictions of epic literature and classical poetry and of heroic exploits. There was growing technical refinement in tile production methods and decoration and the inclusion of artisans signatures suggest the elevated status of the art of ceramics. Tiles no longer imitated metalwork but were themselves imitated in other media.

The center of Iranian industry was in Qashan and the fame of Qashan tiles and ware spread far and wide in the Islamic world, after the thirteenth century. The Persian and Turkish word for tile was *kāshī;* in Arabic, *qashānī* (from Qashan). The period witnesses the experimentation with and the perfection of techniques of underglaze polychromy emphasizing brilliant blues and lustre with its more subdued palette of browns and dark blue for tile decoration.

As early as the end of the twelfth century, tombs in the northwest Iranian town of Maragha demonstrate the progressive introduction of polychrome underglaze tile mosaic for exterior decoration. The emphasis is on brilliantly colored turquoise and dark blue mosaic—purportedly possessing protective magical qualities—in geometric patterns set in sand-colored stucco ground, and also used for Qur'anic inscriptions circumscribing the circular or polygonal brick mausolea. [*See* Inscriptions, *article on* Inscriptions of the Islamic Period.] In luster technique, there was an emphasis on bold design rather than on precision. Because luster did not survive weathering, the technique lent itself only to interior decoration. Whole walls of secular and religious buildings were covered with luster tiles grouped together in combinations of eight-pointed stars with cross tiles. Large luster-tile slab *miḥrab*s employing conservative Qur'anic quotations and floral arabesque also were popular.

Anatolia, Twelfth–Thirteenth Century. The Seljuq Turks introduced tile production to Anatolia (Asian Turkey) from Iran and achieved perfection of it in the thirteenth century. The usage of tile decoration in Anatolia rejected tile for exterior decoration and restricted its use to the interior of buildings. The Karatay Medrese (Ar., *madrasah;* theological school) in Konya in central Anatolia of 1252 monumentally deploys tile mosaic in the large Qur'anic inscription that circumscribes the dome and in the floral arabesque and Kufic style inscriptions of the Turkish triangles supporting the dome (see figure 1). The favored colors in

(Courtesy B. St. Laurent)

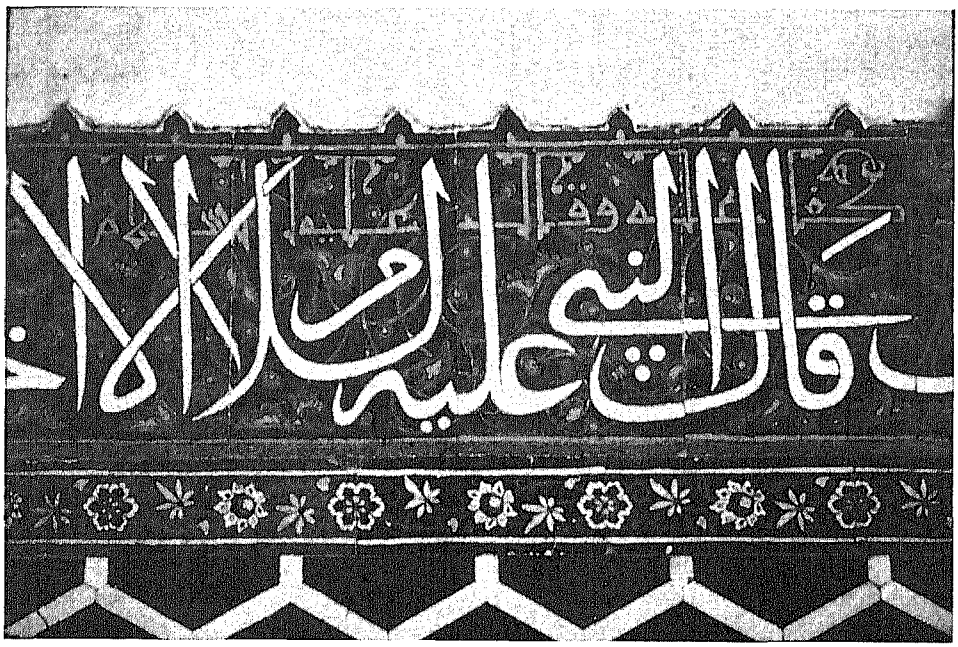
Anatolia are black, turquoise, and dark blue on a white stucco field.

Fourteenth–Seventeenth Century. Tile for architectural decoration flourished in fourteenth–seventeenth-century Ilkhanid (Mongol), Timurid, and Safavid Iran; and in the Ottoman Empire in the fifteenth and sixteenth centuries. The princely art of decorated tiles developed in Iran in the previous two centuries evolved to a major royal art form. In Iran, there was a continuity of development from the Seljuq tradition in the Ilkhanid period to more profuse and elaborate usage of tile decoration in the tomb of the Ilkhanid ruler Öljeitü in northwest Iran. The Timurids in Iran expanded the vocabulary, palette, and extent of usage, with entire buildings sheathed both inside and out with a revetment of tiles and tile mosaic, culminating in the grander scale of the royal Safavid tradition and exemplified in the seventeenth-century Masjid-i Shah or Royal Mosque of Isfahan. [*See* Isfahan.]

The early Ottoman Empire, rather than continue with the method of the Seljuq Turks, rediscovered the Persian tradition of tile revetment for the interior of monumental buildings. In 1420, Sultan Mehmet I brought Persian craftsman to his capital Bursa to decorate his royal mosque and tomb complex called the Green Mosque. The fifteen foot *mihrab* in *cuerda seca* and tile mosaic techniques, the green and gilt tile dadoes, bordered by delicate inscription bands (see figure 2) and foliate arabesque in blues, greens, and yellow with a touch of white of the mosque interior, and the royal pavilion testify to the highest quality of Persian craftsmanship and include the signatures of Persian artisans. In exception to the Turkish proclivity for interior tile decoration, the exterior of his tomb is also covered with turquoise tiles. In the sixteenth century, the workshops of the town of Iznik crystallized the distinct and grand Ottoman imperial style apparent in the decoration of the mosque of Rustem Pasha and the Süleymaniye Mosque in Istanbul. Tile mosaic is abandoned to the exclusive use of porcelainlike square tiles, an innovation of this period, and large rectangular tile panels. Carnations and tulips in red, purple, green, and yellow proliferate on a white ground surrounded by the graceful calligraphic leaves that define the Iznik style.

Thus, an Islamic imperial tile tradition that originates from the ancient Near East witnesses an initial revival in ninth-century Iraq, with a subsequent effloresence as a princely art in twelfth- and thirteenth-century Iran and Anatolia. In fourteenth- and fifteenth-century Ilkhanid and Timurid Iran, tile becomes a popular medium for royal monumental architectural decoration displaying regional technical and stylistic distinctions. The royal workshops of the Safavids and the Ottomans produced the grand imperial



TILE: Decorative. Figure 2. *The Green Mosque (Yeşil Cami) in Bursa, Turkey.* Interior view of the royal mosque of the early Ottoman Sultan Mehmet I built in 1420, showing the top of a tile dado in one of the iwans. TIMNAʿ (modern Hajar Kohlan), site in Arabia located about 15 km (9 mi.) north of Hajar Bin Humeid beyond the town of Nuqub (15°02′02″ N, 45°48′4″ E). It was the capital of the Kingdom of Qataban, one of the five kingdoms in pre-Islamic South Arabia, which included Saba' (biblical Sheba), Ḥadhramaut, Ausan, and Maʿin. It occupies the west bank of the Wadi Beihan, which flows northward, draining runoff water from the northern slopes of the southern mountains. The mound is oval, with perhaps 10 m of stratified occupation debris, and covers an area of about 19.48 ha (52 acres), with its long axis oriented northeast–southwest. The Timnaʿ cemetery occupies the western slope of a small rocky hill some 500 m north–northeast of Timnaʿ known locally as Ḥeid Bin ʿAqil. The site's identification as Timnaʿ was established in 1924 by Nikolaus Rhodokanakis, while assembling all known Qatabanian inscriptions.

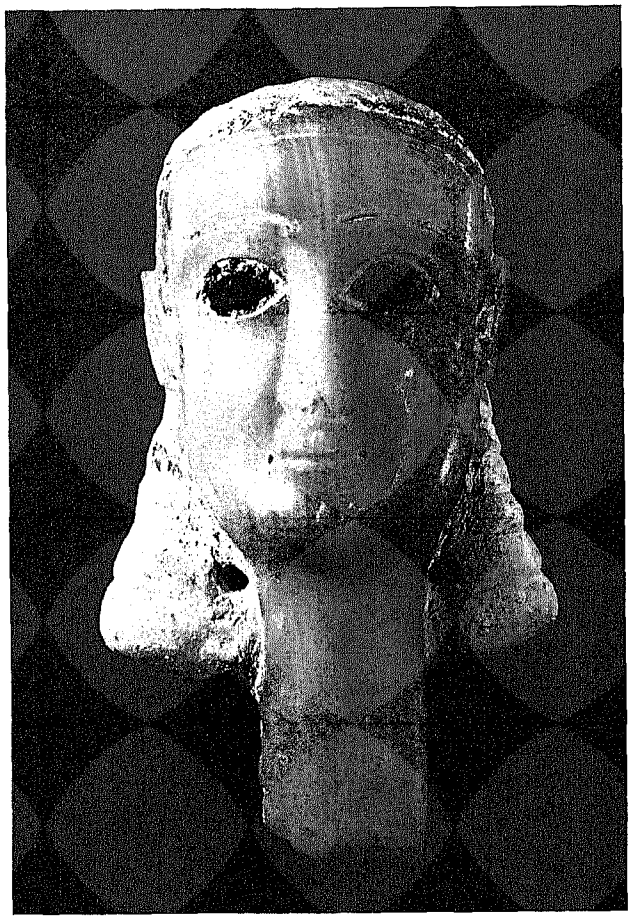
In 1950 the American Foundation for the Study of Man (Wendell Phillips, president, and William Foxwell Albright, archaeological director) began an excavation of the site, assisted by Albert Jamme, Alexander M. Honeyman, Friso Heybroek, Charles Inge, and Richard LeB. Bowen, Jr. During the 1951 season, E. Burcaw supervised digging in the South Gate area; James Swauger, assisted by John Simpson, supervised work at the Temple site; and Robert Shalkop was in charge of excavating the Timnaʿ cemetery. Gus Van Beek assisted in drawing plans of the South Gate and cemetery areas.

South Gate. Only the uppermost stratum of an area measuring about 61.5 m NNW-SSE × 48.0 m WSW-ENE was excavated. This area contained the remains of the South Gate, a small plaza, two streets, and several large buildings. The gate consisted of two towers flanking a flagstone-paved passage. Both towers were constructed of enormous coursed blocks, and their outer wall faces were covered with South Arabic inscriptions. In the east tower, a stairway led to an upper story. Two stone benches—each one built against one of the towers—faced each other across the passage.

The gateway gave access to the open plaza, from which two parallel streets led northwestward separated by Building B (Yafash House), at the base of which two magnificent bronze sculptures, each featuring a lion ridden by an infant male child, were found. Fronting the westernmost street was Building A (Yafaʿam House). Across the easternmost street Building D (Hadath House) consisted of two or more stories. These names are known from inscriptions on the buildings themselves, a relatively common feature in pre-Islamic South Arabia. Farther along and neighboring Building D, Building C, as yet nameless, was constructed of the finest ashlar masonry found at Timnaʿ. Above the ashlar courses of the first floor, Buildings D and perhaps C may have featured post-and-beam construction, utilizing a framework of heavy wooden beams enclosed with curtain walls, judging from the many burned and broken beams in the debris. Remains of roughly contemporary buildings at Shabwa with fragments of charred wooden beams still in place suggest that this type of construction was well known in the region. [*See* Shabwa.]

Temple. The Temple structure (about 49.0 × 41.5 m) is oriented on an east–west axis and consisted of three sections: the Temple itself, a court, and possible storerooms. The Temple is the major and oldest section on the east end and is built of massive blocks, larger than those of the South Gate towers. In its walls was a series of huge recessed niches. The Temple was ascended through a marble-paved court via a marble staircase (about 6.5 m wide) with four steps. The main entrance to the court was also via a marble staircase, but of nine steps, on its north side, and a marble pavement extending at least another 7.7 m. Adjacent to the court and against the north wall of the Temple stood a large stone water tank. Several of the paving blocks in the court were inscribed, each with a South Arabic letter; the arrangement of the letters, similar to that of the Ethiopic alphabet, probably preserves the earliest known order of the South Arabic alphabet. A series of probable storerooms surrounding the court on the south, west, and north sides was represented by a series of parallel crosswalls. A deep sounding disclosed the walls of an earlier structure below the massive blocks of the Temple. The earlier structure had been built of much smaller blocks and its wall had buckled outward slightly



TIMNAʿ (ARABIA). Figure 1. *Calcite alabaster head from the Timnaʿ cemetery.* Hair is styled by an overlay of plaster. The holes on either side of the neck probably carried the necklace shown in figure 2, from the same tomb. (Courtesy G. W. Van Beek)

from the weight of the later structure. It has been suggested that the earlier structure was a palace rather than a temple, but the evidence is inconclusive.

Cemetery. On Ḥeid Bin ʿAqil, a rock hill about 0.5 km north of Timnaʿ, Honeyman and Shalkop excavated the Timnaʿ cemetery in 1950 and 1951, respectively, covering an area of about 2,550 sq m. In area A, on the lower slopes, three successive mortuary chapels ascended the hill, the earliest built of mud and the later ones of stone. A large mausoleum complex occupied area B, about three times larger in area than the chapels. The mausolea share a common plan, featuring square burial structures of rubble, fronted on a central aisle, each structure consisting of four or five parallel partition walls divided into two or three vertical chambers (about 2.0 × 0.75 m) to accommodate individual burials. Burials of prominent individuals seem to have been accompanied by a stone box either with an alabaster head portraying the deceased or a relief inscribed with the individual's personal and family names. The stone box was closed by one- or two-leaf doors and securely fastened by a vertical peg that pierces the roof and is held in place by a horizontal pin. The finest alabaster head yet discovered came from such a tomb (see figure 1); from that same tomb came a gold necklace in the form of a crescent curving below a solar disk and bearing the name *Hagarlat ʿAlay Fariʿat* (see figure 2); it had probably been attached to the alabaster head through two holes between the line where the neck and hair meet. All the tombs excavated had been plundered; although few human bones were found, some of the tombs contained ashes, indicating the practice of cremation. Objects such as highly stylized ibexes, bulls, and diverse architectural fragments provide a view of a wealthy culture that stressed the arts of sculpture, architecture, and writing. The many objects that were imported illustrate a range of origins: Rome, Greece, Asia Minor, the Levant, and Ethiopia. By 1991, little remained of these structures because Timnaʿ was largely robbed of all visible building stone to build houses, except for the massive blocks of the Gate Towers and the Temple.

TIMNAʿ (Ar., Wadi Meneʿiyeh), valley in the Negev, part of the ʿArabah, located about 30 km (18.5 mi.) north of the Gulf of Eilat/ʿAqaba. The area has been exploited over the centuries for its deposits of copper ore. Much investigated by nineteenth and twentieth-century explorers, Timnaʿ was extensively surveyed and excavated between 1959 and 1990 by Benno Rothenberg, joined after 1964 by an interdisciplinary team of scientists and sponsored chiefly by the Haaretz Museum in Tel Aviv.

Nearly a dozen mining camps and at least one smelting site have been investigated. They date from the Late Chalcolithic to the Roman and Islamic periods, but especially to the Late Bronze Age, when Egyptian (nineteenth–twentieth dynasties) expeditions and garrisons were maintained there.

The Timnaʿ mines themselves comprise deep vertical shafts extending as deep as 35 m—narrow, horizontal galleries driven deep into the rock, sometimes branched, and saucerlike depressions in the hillsides. Such sophisticated shaft-and-gallery mining techniques as those discovered at LB Timnaʿ had hitherto been unknown before the Roman period in Europe.

One Egyptian New Kingdom mining site (site 30) was a very large smelter, with three phases of use, surrounded by

a defensive wall. It was in use into the Early Iron Age, with a brief reuse in the tenth century BCE. There, as elsewhere at the site, the painted so-called Midianite and handmade Negebite wares were found alongside local pottery.

The most spectacular discovery was an Egyptian temple at the base of the sandstone massif long known as Solomon's Pillars. Its major phases date to the time of Seti I (1318–1304 BCE) and Rameses II (1304–1237 BCE); it apparently was destroyed by an earthquake (site 200). The original shrine (stratum III) was rectangular in plan, with a small raised naos and a niche on the back wall. Later additions were a side chamber, a row of monoliths, and stone elements, such as a Hathor pillar and various altar fragments that were in secondary use (stratum II). A tented sanctuary (stratum I), perhaps used by Midianites after the Egyptian abandonment (c. mid-twelfth century BCE, was attested by fragments of heavy red and yellow textiles and a gilded copper serpent. The earlier Egyptian deposits included large quantities of pottery; votives in stone, alabaster, faience, terra cotta, bronze, and gold; and animal and Hathor figurines, plaques, jewelry, scarabs and seals, and a small sphinx.

Nelson Glueck's explorations in Wadi Timna' in the 1950s and his excavations in the late 1930s at the site of Tell el-Kheleifeh (which he identified as a Solomonic period smelter and seaport) connected the Timna' mines popularly with the fabled "King Solomon's mine." [*See* Kheleifeh, Tell el-.] For the most part, however, mining activity at Timna' was Egyptian-sponsored and mostly Late Bronze Age in date.

WILLIAM G. DEVER

TOMBS. In the ancient Near East tombs took on a number of different forms that reflected the nature of building materials, topography, social status, ethnic or tribal affiliation, and spiritual beliefs. In broad, symbolic terms, tombs

were apparently perceived as simulations of either the womb (implying the expectation of rebirth) or a dwelling (with ancestors) or both.

From the meager prehistoric evidence (from the Paleolithic to the Neolithic Ages) tombs consisted of simple pit burials inserted under the living surfaces of caves (in the Paleolithic) and huts (in the Epipaleolithic and Neolithic). By the Pottery Neolithic, infants were being interred in ceramic jars (Tel Dan, Tel Teo in the Hula Valley of Israel, Tel Qatif in the Gaza Strip) and adults in tumulus or cairn tombs (Eilat).

The Chalcolithic period saw the crystallization of several new tomb types and burial practices. Communal burial grounds were separated from settlements, though the tradition of intramural infant inhumation continued. The rock-carved or natural cave tomb became the standard type and remained so until the Islamic period. Constructed tombs in the form of tumuli (at Eilat, Shaʿar ha-Golan, Neveh Yam), and grave circles (the *nawamis* in the Sinai Desert and in the Shiqmin cemetery) became more commonplace. The pottery or stone ossuary came into vogue as the preferred receptacle for secondary interment of selected bones. [*See* Ossuary.] Stone-lined and capped cist tombs are found in some places, the most prominent example being Adeimeh, across the Jordan River from Jericho.

In the Bronze Age Levant the rock-carved or cave tomb was by far the most common type for adults and juveniles. This type reached its classic form in the shaft tombs at sites such as Bab edh-Dhraʿ, Jericho, and Jebel Qaʿaqir. In the steppe and desert regions, dominated by nomadic or semi-nomadic pastoralists, tumuli tombs were the standard practice, while the dolmen tomb tradition developed along the Syro-African Rift Valley, in tandem with the tumulus and rock-carved tomb. [*See* Pastoral Nomadism.] At Bab edh-Dhraʿ, early Early Bronze I shaft tombs were gradually supplanted by above-surface, round burial structures (EB IB–EB II) and finally by large rectangular "charnel houses" (EB III). In the EB IV, the shaft-tomb tradition was resumed. However, the Bab edh-Dhraʿ above-surface burial structures and the length of the burial sequence are unique thus far for the Early Bronze Age.

The tomb forms of the Early and Intermediate Bronze Ages carried through into the Middle and Late Bronze Ages, but with several innovations. The constructed, corbeled tomb (at Tel Dan, Tel Kabri, Megiddo, Jericho, Tell ed-Dabʿa) and the subfloor burial of infants in jars were imported (or reintroduced in the latter case) into the southern Levant from Syria/Mesopotamia. The bilobate cave or shaft tomb made its appearance toward the middle of the Middle Bronze Age, particularly along the coast at sites such as Tell el-Farʿah (South). In the Late Bronze Age, multiple burials in cave and shaft tombs continued as before in the high-

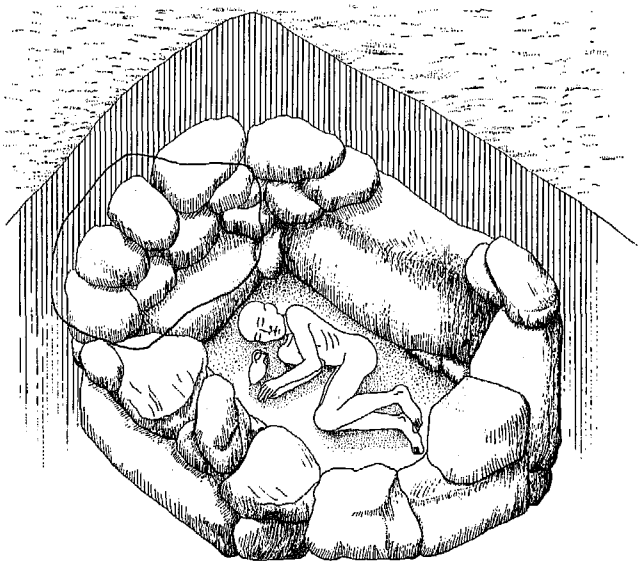
TOMBS. *Stone chamber tomb.* (From T. E. Levy, ed., *The Archaeology of Society in the Holy Land*, New York, 1995)

lands, but along the coastal zone individual cist tombs and pit burials became the norm. At the same time, rectangular chamber tombs with introductory passages (dromos), benches, and the occasional supplementary room appeared (at Tell el-Farʿah [South], Tell el-ʿAjjul, Beth-Shean, and on Cyprus), as did clay coffin burials (larnakes and anthropomorphic coffins)—all of which have been interpreted as exhibiting various degrees of foreign influence (Syrian, Anatolian, Mycenaean, Cypriot, Egyptian).

In the Early Iron Age (1200–1000 BCE), tomb types and burial practices seem to have continued LB traditions on the coastal plain and in lowland valleys. The highlands are strangely devoid of evidence for mortuary behavior, unless LB cave tombs were still in use. For the Iron Age II, most of what is known about tomb forms comes from Judah, especially Jerusalem. The classic Judahite tomb resembles the rectangular LB chamber tombs of the coast (see above), with forecourts and raised benches or troughs to support or contain the cadaver, Hathor wig-shaped headrests, and subsidiary repositories for the secondary collection of bones moved to make room for more recent inhumation. This configuration is also reminiscent of the typical quadripartite dwelling plan typical of the period throughout Israel. [*See* Four-room House.] Some of these tombs include architectural details carved into the rock and identifying, warning, or incantory inscriptions. The northern part of the inland Levant is somewhat lacking in tombs. Tombs on the Phoenician coast (e.g., Achziv) are mainly shaft tombs and cist burials, continuing Bronze Age traditions that lasted into the Persian period. Kraters containing cremations are also characteristic.

Three general tomb types have been discerned for the Persian period: (1) rock-hewn chamber tombs containing benches or troughs that continue Iron Age traditions; (2) built, dug, or hewn cist tombs; and (3) shaft tombs. The latter two types appear within the Persian period itself—cist tombs being a more eastern tradition (Persia, Mesopotamia, inland Syria) and shaft tombs being a western, littoral tradition (Cyprus, coastal Syria-Palestine). The eastern cist tradition may also include burial in metal or ceramic chests or jars, while the western shaft tradition occasionally incorporates the use of anthropoid sarcophagi, in the Egyptian and Phoenician style.

In the Hellenistic period the loculi ("burial niche," or *kokh* in Hebrew) tomb appeared in northern Egypt and became the dominant type in the southern Levant. Some of the earliest examples are found in the Mareshah (Marisa) necropolis (second century BCE) and in Jerusalem (the tomb of Jason). The other significant class of sepulcher in this period—one that appeared toward the end of the Second Temple period and remained current into the Byzantine period—was the arcosolia tomb, defined by its arched recesses containing burial troughs or benches. Loculi and arcosolia often occur in the same tomb. The dead were placed in coffins or on biers in the loculi, or in troughs or benches under arcosolia. Following a period of at least one year, the fleshless bones were collected and deposited in a charnel room (until the reign of Herod beginning c. 40 BCE) or in ossuaries (from the time of Herod until the third or fourth century CE), made of stone or clay (the latter was more common in the later Roman period). In some cases the dead were interred in stone sarcophagi, but this technique was apparently reserved for the very rich. [*See* Sarcophagus.] Tombs of this period also had benches (for the preparation of cadavers and the placement of ossuaries) and forecourts. They were often sealed by a round, rolling stone (Heb., *golal*). Some, like Herod's family tomb in Jerusalem and the

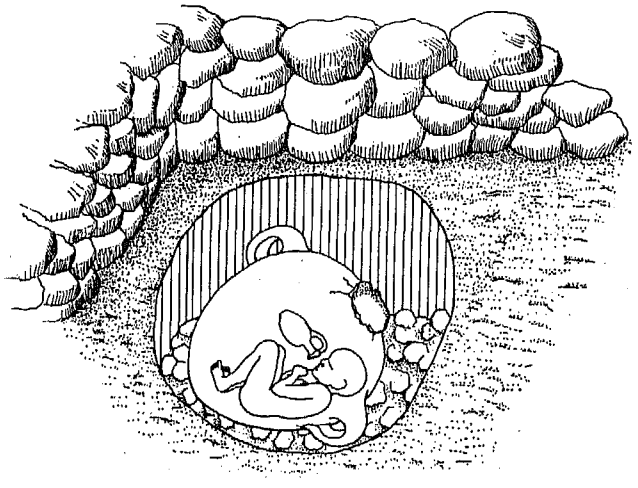


TOMBS. *Stone-faced cist tomb.* (From T. E. Levy, ed., *The Archaeology of Society in the Holy Land*, New York, 1995)

Ḥorvat Midras tomb in The Shephelah of Judah, were paneled with ashlar masonry. The great necropolis at Palmyra included very large and ornate tomb structures of three kinds: subterranean "hypogea" with loculi (the most frequent), tower tombs (originally perhaps serving as monuments for hypogea), and the least common, atrium tombs. [*See* Necropolis.]

The monumental tombs of the Hellenistic and Roman periods were characterized by the elaborate ornamentation of their facades. Monumental Jewish tombs (the best examples can still be seen in Jerusalem and Beth-Sheʿarim) were carved in nonfigural, vegetal, and geometric motifs and included a prominent marker, often in pyramidal or tholos form, called the *nefesh*. The same features, but including figural depiction, can be observed in the tombs at Palmyra and in the Nabatean necropolis at Petra. [*See* Petra.] An important source of information concerning tomb decoration and structure is the ornamentation of stone ossuaries. The remains of tomb paintings are quite rare in tombs of this period; the best (and perhaps only) examples come from the Jericho cemetery excavated by Rachel Hachlili and Ann Killebrew.

In the Late Roman period, two new phenomenon entered the tomb repertoire of Palestine. Alongside the consanguineous loculi and arcosolia tombs, the catacomb necropoli at Beth-Sheʿarim and Beth-Guvrin came into being, comprised of large burial halls and corridors carved in the bedrock and containing the remains of various unrelated families. While many features were retained from the Early Roman period (arcosolia, loculi, sarcophagi, decorative techniques and motifs) other aspects changed: ossuaries were no longer used and burial was primary, unless it concerned bones transported from afar for interment in the Holy Land. Figural motifs, including human ones, became acceptable—even adorning the tombs of rabbis. The use of frescoes became more common as well (at Lohamei ha-Getaot, Abilah, Ashkelon). [*See* Wall Paintings.]



TOMBS. *Jar burial.* (From T. E. Levy, ed., *The Archaeology of Society in the Holy Land*, New York, 1995)

The second development of the Roman period was the mausoleum: generally a square or rectangular planned, above-ground, closed structure containing sarcophagi. These often served as access to subterranean loculi or arcosolia tombs via doorways in their interiors. [*See* Mausoleum.]

For most periods it is usually assumed that extant tombs represent only a portion of the original population. The simple pit burials of the Dead Sea sect as revealed at Qumran, lacking any burial goods, and the cist burials in the Byzantine cemetery at Reḥovot in the Negev testify to the simplicity with which some parts of society may have buried their dead—generally the impecunious or otherwise ideologically inclined. In poorly drained environments that alternate between damp and dry, this type of interment may have virtually disappeared from the archaeological record.

TOOLS. *See* Lithics; Metals.

TOURISM AND ARCHAEOLOGY. In the Near East archaeology and tourism are made for each other, or so they seem. They spring from a common root and share a common past. In the case of antiquities tourism, they pursue a common goal: archaeological remains. Outwardly the two appear highly compatible, even perfectly complementary. Upon closer examination, however, their relationship is highly ambiguous, even problematic. This ambiguity arises from a host of complex issues—political, economic, religious, intellectual—bearing on the relationship of archaeology and tourism and their relevance to society at large (Ucko, 1988, 1989b, 1990). An understanding of this begins with an account of their shared origin and common history.

Origins and History. In the nineteenth century an abiding Western curiosity in the Near East gave rise both to archaeology and to tourism. This curiosity, fed by a mixture of religious enthusiasm and intellectual inquisitiveness, economic cupidity, and political design, generated an overwhelming interest in the antiquities of the Near East. In previous centuries ancient ruins, the objective of nineteenth-century tourists and archaeologists alike, had exerted a powerful attraction on travelers in the region. Herodotus is the best-known though certainly not the first Westerner to visit the pyramids (*Histories* 2.124–128). To label that fifth-century Greek a "tourist," however, would be anachronistic. Tourists and tourism, like archaeology, are uniquely modern.

Tourism is travel for diversion, a modern enterprise made possible by the global reach of rapid, inexpensive transportation and the increasing numbers of people willing to pay handsomely to be diverted. These diversions are of necessity safe and not too strenuous, for tourists dislike unmade roads and civil insecurity. Tourism is not pilgrimage, nor is it exploration, although religious pilgrims and early explorers in the Near East were forerunners of later tourists and archaeologists (Ben-Arieh, 1983).

Explorers like Napoleon's *savants,* Ulrich J. Seetzen, Johann Burckhardt, Edward Robinson, and others were all serious travelers bent on discovery, not diversion. In their arduous and often dangerous travels, they located ancient places and described standing ruins, some of which, like Baalbek, Palmyra, and Petra, were recognizable offshoots of a classical civilization already well known in Italy and Greece. Their discoveries set the stage for what followed.

Throughout the nineteenth century, in a mostly pacific, if not always tranquil, Ottoman Near East, tourism and archaeology flourished side by side. By 1900, Egypt, already extensively explored archaeologically, had become a well-established tourist destination, a transformation wrought by an amenable colonial administration and a flotilla of tourist steamers plying the Nile. Until World War I, the Nile Valley and the Holy Land attracted the majority of Western tourists and most of the archaeologists (Silberman, 1982, 1995; Vercoutter, 1992). After 1918 the dissolution of the Ottoman Empire and the assumption of mandatory powers by Britain and France opened the rest of the Near East to archaeologists and to tourists.

The years between the world wars were halcyon. In Europe and America, museums and learned societies devoted to study of the ancient Near East proliferated, as did university departments that trained students to conduct research on behalf of such institutions. By filling western museums with Near Eastern artifacts, academic archaeologists made the ancient world accessible to the modern. Spectacular discoveries, like the tomb of Tutankhamun, and popularized accounts, like the Chicago Oriental Institute's documentary film *The Human Adventure* shown across the United States in the 1930s, widened the general public's knowledge of the ancient Near East, knowledge that translated into a penchant for travel. While there remained remote corners like highland Yemen and interior Arabia, large portions of the Near East lay open to travelers and scholars alike. For both, curiosity prompted access and access piqued further curiosity.

During the late 1930s and 1940s, civil unrest and the global disruptions of World War II, followed by the regional conflicts and population displacements provoked by the founding of the state of Israel, effectively curtailed access to the region but did not check the motivating curiosity. In the more pacific 1950s and early 1960s, despite regional episodes of insecurity and bouts of xenophobia, tourism rebounded and archaeology thrived once again. Continuing discoveries, such as the Dead Sea Scrolls, had the same popular impact as the excavation of Tutankhamun's tomb decades before.

Events after World War II shaped archaeology and tourism in the Near East. The emergence of postcolonial nation-states in the region fomented a new relationship between the two. Foreign archaeologists ceased to be the informal agents of resident colonial administrations and became instead the formal guests, admitted under sufferance and not by right, of sovereign states, which claimed full ownership of the antiquities within their boundaries (ironically a situation akin to the Ottoman period). Tourism came to be regarded as a source of much-sought foreign currency income and something to be promoted as a matter of state policy. Ministries of tourism discerned that antiquities attracted tourists and that antiquities fitted naturally into official schemes to boost tourism and thereby state revenues.

A Natural Fit. The Western experience with the Near East during the previous 150 years prepared the way. Tourism in the Near East was unquestionably regarded as international tourism from the developed West to the developing Near East. Tacitly this recognized economic reality because only travelers from the developed world had disposable in-

come to pay for expensive diversions abroad. (Left aside temporarily was the nearby, potentially large market for local and regional tourism, which could only develop in the aftermath of permanent regional peace.)

International economic development agencies, such as the World Bank, were inclined to see the same natural fit between international tourism and antiquities. International cultural organizations such as UNESCO reinforced this by designating selected archaeological sites as elements of a "world cultural heritage" (UNESCO, 1991). Such designations served to authenticate individual government's claims for the distinctiveness of their cultural heritages and to enhance their country's status as a tourist destination. Such designations also influenced decisions by international donors about funding for programs of archaeological site preservation and promotion and affected how local departments of antiquity planned for preservation (e.g., Wigg, 1994). Recently donor policies have shifted in favor of private over the public sector investment for tourism development, a trend that has enlarged the direct role of private entrepreneurship in antiquities-based tourism in the Near East.

This perception of "natural fit" is the prevailing view on the relationship between archaeology and tourism. *Prima facie,* this opinion is valid. Archaeology discovers and explains significant remains lying unsuspected beneath the surface. Tourism connects these remains with the traveling public's knowledge and imagination in ways that make them at once interesting, intelligible, and diverting. This perception is reinforced by the indisputable fact the ancient remains do attract tourists and tourism does makes money. Although the fit between tourism and archaeology seems natural enough, however, the two are in fact independent, even divergent, phenomena.

Disjunction of Tourism and Archaeology. Tourism is hardly indispensable for archaeology. For most archaeologists, tourism is something that happens after they leave a site. Typically archaeologists, whether foreign or local academic researchers or antiquities department personnel, play a minimal role in preparing sites for tourism and none at all in the economic decisions leading to such preparations. Archaeologists, moreover, do not go to ancient sites as tourists seeking diversion but as professionals seeking information. With the exception of sites actively under excavation, the information they seek is not to be found in situ on overgrown, eroded mounds, but rather in published excavation reports, field records, drawings, photographs, and museum collections.

Archaeology is not indispensable to tourism. Ancient monuments were known and enjoyed, if not properly understood, long before the advent of archaeology. For millennia before they were investigated scientifically, the pyramids were cloaked in a mystery that detracted not at all from their allure. For tourists, the perceived role of archaeology is to expose sites worth seeing. What qualifies as "worth seeing" are usually monumental or otherwise visually spectacular ruins. Tourists (and their guides) are singularly uninterested in ruined farmsteads or abandoned nomad camps; although, as archaeologists rightly insist, these too are important parts of the archaeological record. The problem is that research agendas and tourist itineraries do not necessarily coincide. The touristic appeal of a site may be completely contrary to its archaeological significance.

Prehistoric sites present a particular problem in this regard. They are rarely well preserved (though some exist, e.g., Khirokitia in Cyprus, Çatal Höyük in Turkey) and so require a great deal of interpretation to make them comprehensible to the interested nonspecialist. Two of the largest and most important Neolithic settlements in the southern Levant, Jericho in the Jordan valley and 'Ain Ghazal east of Amman, are decidedly not tourist attractions. Neolithic Jericho, exposed only at the bottom of Kathleen Kenyon's narrow trenches, is mostly buried under meters of later accumulation. 'Ain Ghazal, although unburdened by later occupation, lies in an industrial suburb of the modern Jordanian capital at the intersection of two expressways and opposite a sewerage treatment plant—a decidedly unappealing location. Neither prehistoric site invites more than a cursory notice, if that, from any but the most determined tourist.

Sites in the Near East chosen for touristic promotion almost exclusively have some monumental aspect. They are usually Roman in date (e.g., Beth-Shean, Caesarea, Jerash), or possess some significant connection with particular national histories (e.g., Babylon, Giza, and Masada). Such sites already are part of popular cultural knowledge and in effect sell themselves. Such archaeological sites are ready-made tourist infrastructure, needing only some on-site amenities and adequate advertisement to make them attractions. These attributes are expressly cited in economic arguments for antiquities-based tourism.

Economics of Antiquities-Based Tourism. The contention that antiquities, through tourism, can be made to "pay their own way" sway skeptical economists, who resist altruistic appeals for site protection grounded in abstract principles of cultural-resource management. The logic runs thus: ancient monuments are like natural resources; they are in place and already paid for. The only capital expense required is that of making them accessible and intelligible to tourists. (This effort frequently consists simply of erecting a sign at the site and marking its location on a map.) Antiquities attract foreign tourists and foreign tourists spend hard currency, not just on admission fees, guides, and souvenirs, but also on food, lodging, transportation, and a range of other related services.

There are dangers however, in "digging for tourism." Because investments in touristic development must return a profit, economics may dictate criteria for site preservation

at odds with academic archaeological research. The dilemma is how to balance the rival demands of site preservation and touristic promotion. Site preservation, properly done, serves very long term goals with no immediate (or even eventual) payoff in public attention or financial benefit. Tourism, on the other hand, can excite wide popular interest and earn hard cash. This imbalance means that excavations of sites being developed for tourism are vulnerable to charges that archaeological rigor will be sacrificed for economic gain, not only in unearthing remains but also in post-excavation site restoration.

All excavated sites, whether developed for tourism, require post-excavation protection. The simplest and most economical means is backfilling, although this does not leave much worth seeing on the surface. Consolidation of excavated remains is a minimal measure intended to prevent further deterioration of ruins exposed to the elements. Restoration designed to recreate ruins as they appeared in antiquity is the ultimate and most costly step. Because restoration can bring about profound changes in archaeological remains, questions of whether, how, and how much to restore are fraught with controversy. There are issues of appropriate technical applications, such as what materials are strongest and least obtrusive for structural reinforcement or the most effective way to shelter delicate mosaics. There are philosophical and aesthetic debates over how much to restore and how much to leave to visitors' imaginations. There are economic arguments about the costs of post-excavation treatments in relation to calculated returns on investments for increasingly elaborate restorations. The thorniest question of all is who finally determines the extent of site restoration. This decision is rarely made by archaeologists but often by architects, landscape planners, tourist consultants, and ministry officials with varied, even conflicting aims and ideas. Political or religious forces may also play a role, as when religious proponents insist that ancient houses of worship be reconsecrated for modern use (as occurred at Masada) or politicians decree that excavated structures be refurbished as modern national symbols (as the Iraqis intend for the ziggurat at Babylon). Ultimately, whoever pays for site restoration may dictate not only its shape and scope but also its technical and aesthetic detail (Ucko, 1989c; Killebrew and Hachlili, forthcoming).

Even if the preservation *versus* restoration dilemma can be resolved, antiquities tourism is not without its drawbacks. Ancient sites, despite their apparent solidity, are actually quite fragile. The mere presence of visitors at an archaeological site, no matter how well conserved, can cause damage; and the more visitors, the more severe the damage. This is evident already in Egypt, where pharaonic-period tombs and temples are suffering from the accumulated effects of the exhaled breath and sweating bodies of the thousands of tourists who thread their way through the ruins annually. The impact of increased tourism can extend beyond the site itself into the surrounding environment. At Petra in Jordan, the Sik, the spectacular natural gorge leading into the site, is threatened by clouds of dust churned up by increased motor traffic through it. Efforts are underway to control this situation, but some irreparable harm has already occurred. Archaeological sites that attract too many tourists can fall victim to their own success.

Museums. Museums seem to offer a benign alternative to touristic promotion of sites. Archaeological museums, the distilled essence of archaeological research, constitute a complementary focus for the attentions of both tourists and archaeologists. Moreover, in museums it is possible to present antiquities in protected, interpretive contexts unachievable at archaeological sites. The complex and ambiguous relationship between archaeology and tourism, however, extends even to museums. Understanding that relationship begins again with past history.

National archaeological museums were established in every colonial capital in the Near East—Cairo (1902), Damascus (1919), Beirut (1920), Baghdad (1926), Jerusalem (1929), and Amman (1951). At their founding, they conformed in architecture and arrangement to prevailing metropolitan notions of the preservation and display of antiquities. At independence, they were bequeathed to their respective emergent nation-states along with firmly fixed western notions of what museums should be. With few exceptions, these museums and the ideas behind them have changed little in the intervening years. Today they face manifold challenges: aging physical structures, outdated exhibition galleries, cramped storage facilities overflowing with new finds, chronic understaffing, and persistent underfunding. Despite these problems, national museums in the Near East continue to attract tourists and archaeologists because they remain *the* repositories of their countries' most significant archaeological discoveries.

Archaeological museums established since nationhood, notably in Israel and in the Gulf Arab states, have followed more modernizing trajectories. This situation is also true of smaller local museums and site museums created throughout the region, both those developed by departments of antiquity, such as the Idlib Museum in Syria (which serves as a regional museum and as the Ebla site museum), and those founded by various universities, like the National Maritime Museum at Haifa University and the Museum of Jordanian Heritage at the Yarmouk University Institute of Archaeology and Anthropology.

National archaeological museums (or their parent departments of antiquity) have also originated exhibitions that have traveled outside the region, attracting and informing both tourists and archaeologists. A partial list includes *The Treasures of Tutankhamun* (Egypt, 1976–1979), *The King's Highway* (Jordan, 1986–1987) and *Ebla to Damascus* (Syria,

1985–1987), and *King Herod's Dream* (Israel, 1988–1990). The newly instituted practice of long-term loans of archaeological artifacts to Western museums, such as the Chalcolithic materials lent to the Metropolitan Museum of Art in New York by the Israel Antiquities Authority in 1994, promises to have a similar popularizing and educational effect.

Archaeology, Tourism, and Nationalism. National museums of archaeology and the collections they hold represent the cultural heritage of their respective nations. Cultural heritage is a useful thing for nation-states, providing a sense of national identity and a focus for political solidarity. It is also a commodity that can be sold to foreigners, not as artifacts (though this practice occurs) but as something to be experienced through tourism. The questions remain, which cultural heritage to market and whose national story to tell? In a region as politically, ethnically, religiously fragmented as the contemporary Near East, competing nationalisms can and do make incompatible demands on the custodians of archaeological sites. The presentation of sites, selecting some for preservation and promotion and omitting others, can be politically, religiously or ethnically expressive (Silberman, 1990, Ucko, 1989a). This extends as well to museums, where arrangement and emphasis (as well as omission) in the display of artifacts can be equally significant (Anderson, 1983; chapter 10).

Archaeological monuments are tangible symbols of the past, but as archaeologists know, monuments do not speak for themselves; they must be interpreted. The main aim of archaeological research therefore is to unearth, interpret, and understand the past through its relict material culture. Archaeologists realize that this endeavor is a complex process involving many tentative interpretations. Such tentativeness is difficult to convey appropriately to nonspecialists, who visit archaeological sites or museums in search of simple messages from these tangible symbols of the past.

Future Prospects. Because the success of tourism depends not only on interest and access but also on civil security, it is vulnerable to disruptions that create insecurity. In a region still striving toward peace and stability, tourist clienteles and public images painstakingly built up can be shattered in an instant by violence. That violence need not erupt into war, as it did in 1990–1991 in Iraq and Kuwait. A single savage act is sufficient. Political extremists know this and have in some cases (as in Egypt and Turkey) deliberately targeted tourist facilities or tourists themselves in calculated efforts to topple sitting governments. No tourist seeks such risks, so the effects of violence can be chilling for tourism.

In the mid-1990s, the prospects for peace are promising. Recent moves toward reconciliation in the region will reshape the relationship of archaeology and tourism once more. The opening of once-closed frontiers will eliminate existing artificial limitations to travel and research. Barriers to local and regional tourism, as those that once existed between Jordan and Israel, are already coming down. A stable peace will also make the region a more attractive destination for international tourists. Increasing tourism will contribute to foreign currency earnings, in turn helping spur economic growth, which in its turn will help solidify the peace. There remains the danger, however, that the haste to foster such growth will overwhelm attempts to restrain development for the protection of antiquities. Unregulated development threatens serious impacts on the very antiquities that are objects of archaeological research and touristic interest.

TRANSJORDAN. [*This entry provides a broad survey of the history of Transjordan as known primarily from archaeological discoveries. It is chronologically divided into five articles:*

Prehistoric Transjordan

Transjordan in the Bronze and Iron Ages

Transjordan in the Persian through Roman Periods

Transjordan in the Byzantine Period

Transjordan in the Islamic Period

In addition to the related articles on specific subregions and sites referred to in this entry, see also History of the Field, *article on* Archaeology in Jordan.]

Prehistoric Transjordan

Except for a few unsystematic surveys and excavations earlier in the twentieth century (e.g., Field, 1960; Rhotert, 1938; Waechter et al., 1938; Zeuner, 1957), interest in the prehistory of Transjordan remained relatively casual until the 1960s, when Diana Kirkbride's excavations at Neolithic Beidha (Kirkbride, 1966), near Petra, demonstrated the attractions that this underexplored landscape held in store. Research accelerated in the 1970s (Garrard and Price, 1975–1977; Henry et al., 1981), and since the onset of the 1980s Transjordan has become a principal focus of prehistoric investigations in the Levant.

Ecological Setting. The ecological diversity that characterizes Transjordan's varied terrain can be classified into four major north–south trending environmental corridors (Madany, 1978; Henry, 1986). From west to east, these include: the Rift Valley system, including the Jordan Valley, the Dead Sea basin, and the Wadi ʿArabah. [*See* Jordan Valley.] This region is hot and, for the last two areas, dry; the western highlands and adjacent slopes, which receive the highest precipitation (200–600 mm per year) and enjoy relatively moderate temperature ranges; the steppe region, which, with 100–200 mm of annual precipitation is unarable but which provides considerable pasturage for animals; and the eastern and southern deserts, with less than 100 mm of precipitation and seasonal but sparse vegetation. Much of the northeastern part of this area is covered with basalt flows. Underground aquifers drain a vast region of eastern Transjordan, southern Syria, western Iraq, and northern Saudi Arabia, resulting in the oasis springs and pools of the otherwise arid Azraq basin. [*See* Azraq.]

Changes in climate during the Pleistocene and Holocene epochs strongly influenced the distribution of vegetation in the countryside of Transjordan. Paleoclimatic and paleobotanical information is scantiest for the Lower Paleolithic period, although geological evidence from the Azraq area indicates periods of stable ground cover fluctuating with episodes of erosion and deposits of windblown silts and sand (Besançon et al., 1989; Hunt, 1989), a cyclic phenomenon that has been partially corroborated by undated pollen profiles (Kelso and Rollefson, 1989). [*See* Dating Techniques; Paleobotany.]

The earlier part of the Middle Paleolithic appears to have been a cool period with considerably higher rainfall than at present, although a period of desiccation began about 60,000 years ago, increasing in intensity through the Upper Paleolithic with an interlude of amelioration from about 35,000 to 25,000 years ago. The Epipaleolithic began under mild conditions, but wet and dry intervals fluctuated every two thousand–three thousand years, culminating in the moist circumstances for the Natufian period (Henry, 1986, pp. 8–12). The situation for the Neolithic is frankly confusing, despite the intensity of research in Transjordan and the surrounding region. Claims for increasing regional aridity at about 6000 BCE (e.g., Kenyon, 1979; Horowitz, 1979) seem unfounded on the basis of excavations at ʿAin Ghazal (Rollefson and Köhler-Rollefson, 1989), although modern conditions may have been attained sometime in the fifth millennium. [*See* ʿAin Ghazal.]

Cultural Developments. The earlier phases of the Lower Paleolithic period are poorly known in Transjordan. The only candidate for an Early Acheulean ascription is Abu Khas, near Pella in the Jordan Valley (Villiers, 1983), where artifacts show technological and typological similarities to ʿUbeidiya in Palestine. [*See* Pella; ʿUbeidiya.] However, since the artifacts were redeposited from their original location by erosion, the age is uncertain. The same problems apply to the late Middle Paleolithic collection from Wadi ʿUweinid in eastern Jordan (Rollefson, 1984).

By contrast, Late Acheulean sites are numerous, although only two have been excavated, both in the Azraq basin (Hunt and Garrard, 1989; Copeland, 1991). Results of these excavations and surface collections from throughout the country indicate the existence of three principal Late Acheulean traditions based on variations in tool types and technology: the western Levantine Late Acheulean (cf. Rollefson, 1981), the desert wadi Acheulean, and the Azraq facies (Copeland and Hours, 1988).

In general, it appears that the Late Acheulean inhabitants of Transjordan roamed the countryside in small bands of perhaps ten–fifteen people. One exception to this is the site complex at Fjaje in southern Transjordan, where the distribution of artifacts indicates a seasonal concentration of autonomous groups to "harvest" herds of animals migrating from the Wadi ʿArabah to the Jordanian plateau (Rollefson, 1985).

Middle Paleolithic sites are absolutely abundant throughout Transjordan, accounting for 60 percent or more of the

sites discovered in recent surveys (e.g., MacDonald et al., 1983; Rollefson, 1987a). All of the assemblages conform to the Levantine Mousterian; earlier claims for a Yabrudian presence in northeastern Transjordan have not been borne out by recent investigations (Copeland and Hours, 1988). Two phases of the Middle Paleolithic are evident: an early phase dominated by blades and elongated Levallois points followed by a younger phase, characterized by smaller Levallois flakes and Mousterian points (Copeland and Hours, 1988). Examples from the earlier stage are the excavated deposits from 'Ain Difla in west-central Transjordan, dated by thermoluminescence to 120,000 BP (Clark, 1991), and the assemblages dug from Tor Sabiha and Tor Faraj, south of Ras en-Naqb. [*See* Ras en-Naqb.] The younger phase is reflected by the artifacts from Wadi Enoqiyya just north of Azraq. The transitional (Middle–Upper Paleolithic) Emireh industry is known from several surface exposures in the Wadi el-Hasa (MacDonald et al., 1982; 1983). [*See* Hasa, Wadi el-.]

Despite a decrease in the number of Upper Paleolithic sites, the rate of assemblages per thousand years is comparable to that of the Middle Paleolithic (Rollefson, 1987a, p. 772). The Levantine Aurignacian tradition, based heavily on the production of endscrapers and burins, has been identified in the Ras en-Naqb area, and examples of the blade-bladelet Ahmarian tradition are known from Wadi el-Hasa and the Azraq basin (Byrd and Garrard, 1990).

Tools made on bladelets ("microliths") dominate the inventories of Epipaleolithic sites, although larger tools continue to be important. Chipped-stone assemblages show considerable local diversity in the use of specific techniques and particular configurations of tool types (Henry, 1988; Byrd, 1988), although in general they conform to the Kebaran-Geometric, Kebaran-Natufian sequence of the rest of the Levant. [*See* Carmel Caves.] Settlement diversity is also pronounced during the Epipaleolithic, ranging from small, ephemeral campsites to extensive and deep occupation horizons. The Geometric Kebaran sites Jilat 6 and Kharaneh IV extended over 2 ha (5 acres). Jilat 6 included several dwelling floors, two coated with red ocher, and Kharaneh IV has produced Transjordan's oldest human burials (Rolston, 1982).

Natufian hunter-gatherers ranged from the northeastern deserts (Betts, 1982) to the southern extremes of Transjordan (Henry et al., 1985). Sites vary from small, temporary camps (Byrd, 1989; Gebel, 1988) to large, semipermanent or perhaps permanent settlements (MacDonald et al., 1983; Edwards et al., 1988). The substantial settlement at Wadi Hammeh 27 in the Jordan Valley includes an impressive array of ground-stone artifacts, dwellings, and artwork, as well as several human burials with grave goods. Azraq 18 in eastern Transjordan produced at least eleven burials (Byrd and Garrard, 1990). Although the initial steps leading to agriculture are probably to be found in the Natufian (Gebel, 1984, pp. 7–8), it is not until the Neolithic that definite evidence of human control over plants and animals is found. [*See* Agriculture.]

Two small Pre-Pottery Neolithic A (PPNA) sites have been identifed on the basis of the presence of Khiamian points: Sabra 1 near Petra and Jebel Queisa, south of Ras en-Naqb. In northern Transjordan, the cave of 'Iraq ed-Dubb in Wadi Yabis has produced a broad range of information, including an oval structure, human burials, well-preserved plant and animal remains, and a chipped-stone industry with Khiamian points, all associated with a C-14 date of 8000 BCE; it is not yet clear if the plants include domesticated varieties. [*See* Yabis, Wadi el-.]

The PPNB period witnessed a considerable series of developments, including rectangular architecture (Banning and Byrd, 1987); the domestication of animals (Köhler-Rollefson, 1988; 1989a); local and regional population growth (Rollefson, 1987b; 1989); and an elaboration of ritual practices (Rollefson, 1983a; 1986; Tubb, 1985).

The early PPNB is poorly known in Transjordan, although the phase is signaled by the presence of Helwan projectile points at Jilat 7 in the Azraq area and ad-Daman near Petra. Surface indications of curvilinear architecture and Helwan points at Abu Hudhud in Wadi el-Hasa hold considerable promise for future excavations (Rollefson, n.d.).

The middle PPNB and late PPNB constitute the "classic" Levantine Neolithic period, which can be described in great detail for Transjordan as a consequence of the work conducted at Beidha and 'Ain Ghazal. [*See* Beidha.] The small- to medium-sized middle PPNB farming villages relied on cereal and pulse agriculture and hunting supplemented by goat herding (Köhler-Rollefson et al., 1988). [*See* Cereals.] This mixed-subsistence base was lucrative, at least in the short term (Köhler-Rollefson, 1988), leading to the growth of late PPNB "megasites" such as 'Ain Ghazal, Wadi Shu'eib, and perhaps Basta, all of which extended over more than 12 ha (30 acres). [*See* Shu'eib, Wadi; Basta.] The strain on the delicate ecological systems forced the abandonment of several middle PPNB settlements, however, such as Jericho and Beidha (Rollefson and Köhler-Rollefson, 1989). [*See* Jericho.] The degradation of local environments was exacerbated by demands on forests for fuel to manufacture the lime plaster that was typically used for house floors and walls (Rollefson, 1990b). The removal of trees and brush also eliminated numerous wild-animal habitats, so that by the end of the late PPNB cattle, pigs, and perhaps sheep had been domesticated to replace the variety of disappearing wild species. [*See* Cattle and Oxen; Pigs; Sheep and Goats.]

There is a wealth of evidence pertaining to ritual and religion from middle and late PPNB sites, best typified by the materials from 'Ain Ghazal. Three principal types of human burials occurred, including a subfloor or courtyard, flexed, and decapitated style for most people over the age of a year or so; "trash-pit" burials for about a fourth of the adult pop-

ulation, with skulls left intact with the body; and infant "disposal," with skulls left intact, sometimes occurring as foundation deposits. The first style is probably a family ritual that, along with several plastered skulls, was associated with ancestor veneration (Rollefson, 1983a; Simmons et al., 1990). The second style suggests at least an incipient social hierarchy within the community. The treatment of infants may indicate an absence of "social value" for babies, a possible psychological accommodation for a society that experienced a 30 percent infant mortality rate (Rollefson et al., 1984). [*See* Burial Techniques.]

Human figurines of baked or unbaked clay figured prominently in the lives of the people, and at least one type is clearly identifiable with human fertility. With only one exception, human figurines were broken at or near the neck, a "ritual decapitation" that paralleled the normal burial style. Clay animal figurines were also numerous, and cattle overwhelmingly dominated the identifiable pieces. Several specimens bore cord impressions behind the heads, as if they were haltered, and two cattle figurines were ritually "killed" and buried beneath a house floor (Rollefson, 1986).

The most stunning ritual objects are lime-plaster statues and busts found in three caches at ʿAin Ghazal. One cache has been stratigraphically dated to before 7100 BCE; another produced two C-14 dates of about 6700 BCE; and the third cache can be assigned to about 6500 BCE. It seems probable that the smaller busts (about 45 cm high) represent mythical lineage or clan members, and the taller statues (about 90 cm high) might represent mythical village founders.

The effects of the growing population of Transjordan during the late PPNB, and the sustained degradation of local environments, are reflected in the establishment of hamlets, hunting camps, and specialized "burin sites" in the eastern steppe and deserts. Jilat 7, for example, included several round structures and domesticated barley and wheat but no domesticated animals. The camp at Azraq 31 produced domesticated cereals, probably domesticated sheep or goats, and the remains of numerous wild animals (Garrard et al., 1988). Dhuweila is only one of a large number of late PPNB hunting camps in the Basalt, or Black, Desert, some of which appear to be associated with hunting traps called kites (Betts, 1988b; 1989). Burin sites are known from much of Transjordan (Rollefson et al., 1982; MacDonald et al., 1983), but they are especially concentrated in the arid parts of eastern Transjordan. The function of burin sites remains enigmatic, although they may be associated with pastoral camps (Betts, 1988a).

By the beginning of the sixth millennium, all known farming villages in the southern Levant were abandoned with the exception of ʿAin Ghazal, Wadi Shuʿeib, and perhaps Basta. These PPNC sites, not far from the steppe, continued to thrive as agricultural settlements, but changes in chipped-stone tool production, architecture, subsistence economy, and ritual all indicate major departures from late PPNB norms (Rollefson, 1990a; Rollefson and Köhler-Rollefson, 1993). It appears that some of the village people spent considerable time with their herds in the unfarmable steppe and desert, beginning a process that would eventually lead to fully segregated farming and pastoral economies (Köhler-Rollefson, 1989b). PPNC burials were normally subfloor or courtyard interments, but the skull invariably remained intact with the rest of the body. Most burials also included "offerings" of pig bones (Rollefson et al., 1991). Animal figurines were relatively sparse, and the few PPNC human figurines do not show ritual decapitation, suggesting a major shift away from the religious beliefs of the PPNB period.

With the emergence of the Pottery Neolithic (PN) period, Transjordan witnessed the founding of numerous new farming hamlets in areas not damaged by PPNB ancestors (Kafafi, 1988; Gordon and Knauf, 1987), in addition to maintained occupations at ʿAin Ghazal and Wadi Shuʿeib. It is now clear that pottery manufacture was a locally developed technology and not imported from the northern Levant (Rollefson et al., 1991), although trends within the PN period in Transjordan and Palestine are admittedly difficult to trace. Yarmukian pottery is characteristic of northern Transjordan and differs considerably from the PNA wares and decorative styles found in the Jordan Valley, the Dead Sea basin, and Wadi el-Hasa (Kafafi, 1990; Kenyon, 1979; Bennett, 1980; MacDonald et al., 1983). The pottery from the upper layers at ʿAin Ghazal is entirely Yarmukian, but at Wadi Shuʿeib there are occasional lenses of PNA sherds within the greater Yarmukian stratigraphic sequence (Simmons et al., 1989). [*See* Ceramics, *article* on Typology and Technology.]

The transition from the PPNC to the Yarmukian is well documented at ʿAin Ghazal, and the initial phases of the Yarmukian at the village maintained the agricultural and herding scheme of the preceding aceramic antecedents. Near the end of the sequence at ʿAin Ghazal, however, substantial architecture was replaced by flimsy, hutlike structures, signaling the end of ʿAin Ghazal as a permanent settlement; it was visited instead on a temporary basis, probably in the late summer or autumn, by full-time sheep/goat pastoralists. Contemporaneous sites in the steppe and desert flourished in number (Betts, 1986; Rollefson, 1988).

PN ritual practices are poorly known. Although a number of clay animal and human figurines (including "coffee-bean" fertility examples from ʿAin Ghazal and Tell Abu Thawwab), have been recovered, not a single Yarmukian burial has, implying that off-site cemeteries may have been the rule. A small apsidal structure at ʿAin Ghazal may have served some public function in view of its unique shape and the presence of exclusively fine-ware ceramics (Rollefson et al., 1991), but to what end could not be determined. A late PN site in Wadi Ziqlab, perhaps ascribable to the PNB of the fifth millennium (Banning et al., 1989), yielded several slab-lined burials with accompanying pottery vessels; so far,

however, there have been no comparable examples from elsewhere in Transjordan. [*See* Ziqlab, Wadi.]

Surveys have identified numerous Chalcolithic sites throughout Transjordan's Rift Valley and western highlands, but so far only a few have been excavated. The most productive research has focused on Teleilat el-Ghassul and Abu Ḥamid. It now appears that the Chalcolithic derived from local late Neolithic roots (Hennessey, 1982; pp. 57–58).

Covering about 6.5 ha (16 acres), Abu Ḥamid's small houses (about 25 sq m) and associated storage and processing facilities reflect a rural agricultural village that was probably typical for the Jordan Valley and adjacent slopes. Crops included olives, figs, flax, cereals, and legumes. [*See* Olives.] Domesticated animals consisted of cattle, sheep/goat, pigs, dogs, and ass; hunting and fishing were rarely pursued. [*See* Dogs.] The artifact inventory was generally mundane, characterized by pottery, baskets, and chipped-stone and ground-stone pieces. Clay animal figurines were rare, and only a few violin-shaped human figurines were recovered. To date no human burials have been found at the site, indicating that separate cemeteries were the rule. [*See* Abu Ḥamid, Tell.]

Teleilat el-Ghassul was a huge settlement, extending over more than 20 ha (49 acres). The houses were large (about 35–60 sq m) and regularly situated, suggesting that some central planning authority may have existed (Levy, 1986, p. 88). Not enough information has been assembled to determine if the Transjordanian Chalcolithic settlements were arranged in a hierarchical political system analogous to chiefdoms, but if this was the case, then Ghassul was undoubtedly a chiefly center.

One area of the site revealed a walled sanctuary area containing two buildings with painted walls from which cultic vessels and clay figurines were recovered. The only human burials found were infants; adults were evidently buried outside the settlement, perhaps in a formal cemetery. Evidence of the subsistence economy parallels that of Abu Ḥamid.

Teleilat el-Ghassul may have served as a regional ceremonial center in view of the remarkable murals recovered from several of the buildings (Cameron, 1981). Depicted in vivid primary colors (red, green yellow, black, brown, and white), clusters of geometric shapes, processions of masked humans, and occasional animal designs combine to suggest a magico-religious system under the control of a full-time priesthood that oversaw common rituals and a calendar of special rites. [*See* Teleilat el-Ghassul; Wall Paintings.]

GARY O. ROLLEFSON

Transjordan in the Bronze and Iron Ages

The archaeology of the region east of the central point of the Great Rift Valley is, in many ways, still in its infancy. Biblical connections encouraged early archaeologists to focus on the central territories of ancient Israel, while social and political difficulties in Transjordan discouraged early archaeological exploration. In the 1930s Nelson Glueck pioneered the work in Transjordan by surveying most of the region, discovering many sites unknown before his time and showing that it was possible to do archaeological work there (Glueck, 1970). Only since the 1960s has excavation work on Bronze and Iron Age sites in Transjordan been begun in earnest.

Since the last synthesis on Transjordan (Sauer, 1986), considerable new evidence for the Bronze and Iron Ages has been published, both from surveys and excavations (e.g., Homes-Fredericq and Hennessy, 1986–1989; Ibach, 1987; Miller, 1991). Although closely related to very well-documented archaeological syntheses west of the Jordan River, many of the new finds emphasize significant differences between Transjordan and Cisjordan. The archaeology of Cisjordan can no longer be used as a paradigm for the events east of the Jordan.

Transjordan has three geographic zones running north–south: the east bank of the Rift Valley, including the Jordan River, Dead Sea, and 'Arabah; the arable plateau, which, because of its relatively high altitude, receives enough rain for dry farming, narrowing as it proceeds south; and the eastern desert, which cannot support agriculture without springs and irrigation. Settlement patterns in these three regions are often strikingly different. The Jordan Valley, for instance, tends to have closer connections to the west than it does to the Transjordanian plateau. [*See* Jordan Valley; Judah.]

Early Bronze I–III Periods. The Early Bronze Age begins after the Chalcolithic period (c. 3300 BCE). It is characterized by the growth of urban centers, primarily in the northern part of the country. Although many of the sites are in or very near the river valleys (where water sources could support irrigation agriculture), other sites, including some of the largest ones (e.g., Jalul and Madaba, south of Amman; Tell el-Ḥuṣn, near Irbid), controlled large dry-farming territories on the plateau. This and the presence of the large EB I site of Jawa (North) in the northeastern desert, with its complex system of water management, confirms new evidence from pollen that the climate was most likely wetter than today (Sauer, 1994). [*See* Jawa.] Climate was probably one of the reasons why this period was the most populated in Transjordan until near the end of Iron II (eighth–seventh centuries BCE).

Jawa (North) was one of the most remarkable EB I sites. It was surrounded by a well-preserved city wall and a large gate through which access was gained to a large settlement; outside the walls, in the valleys surrounding the city, a complex series of waterworks included dams, embankments, sluices, and reservoirs. [*See* Reservoirs.] A megalithic tomb, probably a dolmen, from EB IB Tell el-'Umeiri near Amman, that contained twenty burials, twenty complete ceramic vessels, and a few beads has helped to solve the mystery of the chronology and function of similar undated tombs throughout the southern Levant. [*See* Tombs; 'Umeiri, Tell el-; Grave Goods.] Another site, Bab edh-Dhra' at the entrance to the Lisan peninsula of the Dead Sea, has produced one of the largest EB I cemeteries so far uncovered in the Levant containing shaft tombs. It is the type-site for EB I in Transjordan. [*See* Bab edh-Dhra'.]

EB II–III saw the floruit of urbanization. The inhabitants of Bab edh-Dhra' built a strong fortification wall and large buildings on the high points inside the city and expanded the cemetery in EB III with charnel houses (small buildings in which bodies were burned and buried). A neighboring site, Numeira, was a small town preserved by a fire that left more than a meter of burned debris. The most significant EB site in Transjordan, however, is Zeraqun, northeast of

Irbid. [*See* Zeraqun, Khirbet ez-.] It contains a holy precinct with twin temples and a round sacrificial altar with stairs similar to the complex of temples at Megiddo in modern Israel. [*See* Altars; Megiddo.] There is also a large building complex (possibly a palace), a stepped water shaft descending for more than 100 m from a scenic cliff face overlooking the Yarmuk River valley, and strong defenses surrounding an extensive domestic settlement.

The EB material culture was similar to that west of the Jordan, suggesting close cultural and possibly ethnic connections. Within the ceramic assemblage, several forms are widespread, such as holemouth jars and cooking pots, large pithoi with flaring rims and rope molding around the upper shoulder, high-handled juglets, hemispherical bowls, and band painting (in EB IB). Among the weapons, mace heads were frequent. [*See* Weapons.] After pottery, the objects found most frequently are stone grinders for food production. The period's monumental architecture resembles that appearing east and west of the Jordan River in the temples and altars at Megiddo and Zeraqun. The region's domestic architecture, however, is not uniform except that, at most EB sites, such as Tell el-ʿUmeiri, houses are conceived as compounds with living, storage, stable, and courtyard spaces combined into a single housing complex. Such compounds reflect the integration of dispersed agricultural settlements into large urban sites, perhaps for security reasons. Artistically, seal impressions in Transjordan are similar to those found in Cisjordan with geometric designs rolled over pottery by a cylinder seal.

Early Bronze IV (or Middle Bronze I) Period. Toward the end of the third millennium (c. 2300 BCE), urbanism decreased in favor of nomadism. [*See* Pastoral Nomadism.] Large cemeteries at sites with no settlements, but near perennial water (e.g., Bab edh-Dhraʿ, Pella, Tiwal esh-Sharqi, Amman), attest to the nomadic element. [*See* Pella; Amman.] Settled sites in the Jordan Valley and the southern part of the region are primarily not large urban centers, but small agricultural villages and towns. The conversion from the sophisticated urbanism of EB II–III to that of pastoral nomadism in EB IV was probably caused in considerable part by a drying of the climate—drier even than today.

The largest site from this period in all of the southern Levant is Khirbet Iskander in Wadi el-Wala, north of Wadi el-Mujib. [*See* Iskander, Khirbet.] It is the only truly fortified site with a city wall, defensive tower, and gate so far excavated. Tell Abu Niaj, in the northern Jordan Valley, was one of the small villages. Its neighbor and similar site, Tell el-Ḥayyat, produced an uninterrupted transition to the Middle Bronze Age. [*See* Ḥayyat, Tell el-.] Other small settlements include Tell Iktanu in the southern Jordan Valley; ʿUmeiri; Lehun and ʿAroʿer, on the north rim of Wadi el-Mujib; and Ader and Khirbet Ḥabaj, near Kerak. [*See* Iktanu, Tell; Lehun; ʿAroʿer.] Both Iskander and ʿUmeiri also included nearby cemeteries.

Although the EB IV lifestyle was drastically different from that during the period's earlier stages, the material culture still retained primarily EB traits. The pottery was handmade, with forms that naturally arose out of earlier ones. Unlike the universalism of the EB I–III ceramic forms, this period saw the rise of families of pottery that can be isolated to regions (for the Amman region, cf. Palumbo and Peterman, 1993). Many of the tombs contained copper weapons, such as daggers, along with pottery; most of the burials were secondary. [*See* Burial Techniques.]

Middle Bronze Age. Urbanism began to develop again in about 2000 BCE, heralding the Middle Bronze Age. However, Transjordan did not experience the same growth patterns as Cisjordan. Glueck (1970) postulated that there was a significant gap in occupation on the southern Transjordanian plateau during the Middle and Late Bronze Ages. Although the length of the "gap" Glueck proposed is no longer argued, there certainly was a reduction, compared to the flourishing Early Bronze Age. A wetter climate allowed the growth of new urban centers, often on top of EB sites, especially in the Jordan Valley and on the northern and central plateaus, but there was still very little occupation in the southern regions. Urban centers on the plateau were similar to those in Cisjordan, but there tended to be more space between them.

The major excavated sites are primarily in the Jordan Valley, where there was closer communication with the prosperous west. Pella, in the north, contained an often-rebuilt brick city wall and burials within the city as well as outside, in large cemeteries. A temple with thick walls and small houses were found at Ḥayyat. At Tell Deir ʿAlla, in the central Jordan Valley, walls were preserved for more than 2 m in height, with a possible rampart against the city wall; at Tell Nimrin, in the southern part of the valley, there is a very deep, bricky deposit with several phases visible in a road cut. [*See* Nimrin, Tell.]

On the plateau, the Amman citadel and ʿUmeiri have produced ramparts similar to those in the west; ʿUmeiri's rampart includes a dry moat at the bottom. The fact that MB pottery has been found in quantity at many other excavated sites (Abu Snesleh, Abila, Jerash, Deir ʿAin ʿAbata, the Baqʿah Valley, Mekhayyat) and in surveys throughout northern Transjordan, including the eastern desert, suggests this period will become much better known. [*See* Abila; Jerash; Baqʿah Valley.] Jawa (North) contains a fortress above the EB ruins that still preserves corbeled roofing stones.

It may be that MB urbanization only slowly reached the plateau. The best-documented plateau site is ʿUmeiri, but its remains are from the very end of the period. At several locations, EB IV shaft tombs have been found reused early in the period by MB IIA burials. It may be that the pastoral lifestyle of EB IV continued into the beginning of the Middle Bronze Age on the plateau. Elements of MB material culture resemble those in Cisjordan, including finely made pottery,

often with white or cream slips and a reddish-brown painted design called chocolate-on-white ware that begins near the end of the period.

Late Bronze Age. In Cisjordan the Late Bronze Age began in about 1550 BCE. There is so little excavated material from this period in Transjordan that there is no way to support or reject this date. Along with an apparently drier climate, the number and quality of sites diminish in the Late Bronze Age and remain virtually absent from the southern part of Transjordan. In many respects, the period is a continuation of the Middle Bronze Age. Ceramic forms continue but in degenerated wares and painted patterns. The international trade represented by imported items in Cisjordan and the Jordan Valley is only weakly apparent on the plateau.

The major excavated sites are in the Jordan Valley. Pella produced finds primarily from tombs, but the site is well known from the Amarna letters, and Deir ʿAlla contained a small shrine from late in the period. [*See* Amarna Tablets; Deir ʿAlla Inscriptions.] Other deposits occur at Tell es-Saʿidiyeh and Abu Kharaz. [*See* Saʿidiyeh, Tell es-.] Tombs were excavated at Kataret es-Samra in the south. On the plateau, Umm ed-Dananir in the Baqʿah Valley included burial caves and possibly a square temple. The old Amman airport held a small square sanctuary (possibly similar to that at Umm ed-Dananir) that may have been used for human sacrifice or funerary functions, including cremation; this site contained most of the imported pottery and objects so far found on the plateau. [*See* Amman Airport Temple.] Other materials in secondary context have come from Abila and Qwelbeh, near Irbid, and Jerash. In the region east of the Dead Sea, ancient Moab of the Bible, surveys have found considerable evidence for LB occupation, perhaps even heavier than in the Amman region. [*See* Moab.] However, south of Wadi el-Hasa virtually nothing has appeared either in excavations or surveys. [*See* Hasa, Wadi el-.]

Toward the end of the Late Bronze Age, a fresh wave of settlements began that continued into the following Iron I period. Excavated sites include Irbid, Tell el-Fukhar (near Irbid), the Baqʿah Valley, ʿUmeiri, Ḥesban, and possibly Madaba (based on tombs). [*See* Ḥesban; Madaba.] These sites are not continuations of the MB and earlier LB sites, but include, along with late LB pottery and objects, pottery that is also akin to the Iron I, such as large quantities of collared pithoi. It is likely that these sites represent the settlement processes of the nomadic groups that eventually became the national groups of Transjordan known from the Bible and other literary sources: Gileadites, Ammonites, Moabites, and Israelites.

Iron Age I. Beginning in about 1200 BCE or slightly earlier, the Iron I period is characterized by a rapid rise in the number of settlements throughout the plateau, except south of Wadi el-Hasa, as the climate seems to have become slightly wetter. The settlements that began toward the end of the Late Bronze Age continued. Edom probably existed as a nomadic tribal group, and parts of Midian may have come into the southern portions of Transjordan from the Hijaz. [*See* Edom; Midian.]

The Philistines and Canaanites most likely shared a large part of the Jordan Valley, where the major urban centers were located. [*See* Philistines; Canaanites.] Tell es-Saʿidiyeh included a large courtyard building that may have been a governor's residence; and the covered staircase that descended to the water table on the north slope of that site was an important public feature. At Tell el-Mazar, in the central valley, vessels from the Phoenician coast and a few from Egypt were imported in the eleventh century BCE; a large courtyard building from the tenth century BCE that contained cultic ceramics (chalices, a cult stand) was also found there. [*See* Mazar, Tell el-; Phoenicia.] At Deir ʿAlla, extensive remains from twelve phases were found, including Philistine pottery, metallurgical tools for bronze production, and possible city walls with a gate. There was also evidence of an earthquake in about 1200 BCE. [*See* Deir ʿAlla, Tell.]

On the northern plateau is the ancient mound of Irbid, with a cemetery and a possible city wall. [*See* Irbid.] Recent excavations at Fukhar have produced domestic dwellings with large quantities of collared pithoi and the only Philistine potsherd so far found on the plateau. The sites in the Amman area include the Baqʿah Valley, with its cave burials; Saḥab, with domestic dwellings and collared pithoi; Ḥesban, with a cistern and a rock-cut water or defensive installation; and ʿUmeiri. [*See* Saḥab; Cisterns.] The latter has the most coherent fortification system from this time in the southern Levant, including a dry moat, a rampart, and a casemate wall; houses inside the wall were preserved up to 2.5 m high. At ʿUmeiri more evidence was found for the 1200 BCE earthquake (see above). Although ʿUmeiri was larger than most highland villages, and certainly much better fortified, its material culture represents that of the earliest highland villages in Cisjordan, including about ninety reconstructable collared pithoi.

In Moab, small-scale excavations have unearthed village sites at Lehun and ʿAroʿer along the north rim of Wadi Mujib. Baluʿ, Medeinet el-Muʿarrajeh, and Medeinet el-ʿAliya on the south rim were more major sites, but both seem to belong to near the end of Iron I. [*See* Baluʿ.] Medeinet el-Muʿarrajeh may have copied the idea of a dry moat from ʿUmeiri. Only soundings at very small, shallow sites have produced Iron I pottery in Edom, south of Wadi el-Hasa at Baʿja and Sela. It is likely, however, that other sites will produce Iron I remains in the future. Other excavated sites with secondary or small deposits include Nimrin, Abu el-Kharaz, Abila, Jerash, and Feinan. [*See* Feinan.] Cemeteries were found at Saʿidiyeh, Mafraq, and Madaba. Surveys throughout Transjordan have shown Iron I sites frequently, in all regions but on the southern plateau.

Two assemblages of material culture can be discerned related to geographic regions and lifestyle. The sites in the Jordan Valley contain finds related to the major Canaanite and Philistine urban cultures of the coastal plain and large valleys in Cisjordan. They tend to contain imported pottery and objects and public buildings. The sites on the plateau are much poorer, with a limited assemblage of finds similar to the highland village settlements in Cisjordan. Several scholars have suggested tentative related tribal backgrounds for the groups inhabiting those sites in both Cisjordan and Transjordan, noting the similarity of finds at ʿUmeiri and the villages of the hills north of Jerusalem. [*See* Jerusalem.]

Iron Age II. Although early archaeologists placed the beginning of the Iron II period after the invasion of Shishak (Sheshonq) in about 921 BCE, most Israeli scholars now begin it in about 1000 BCE, with the commencement of the Israelite monarchy and the new millennium. There is not enough evidence from tenth-century BCE Transjordan to confirm this new periodization or not. Indeed, the evidence from well-documented excavations for sites before the eighth century BCE is not strong. This does not mean that occupation at that time was weak, but rather that the excavation of that material has not yet taken place.

The Iron II period is characterized by the rise of the monarchies of the small national groups on the plateau: Aramean Damascus, Ammon, Moab, and Edom. [*See* Damascus.] They enabled a gradual but steady rise in prosperity, exemplified by a much richer and finer material culture toward the end of the period. There was also a rising national awareness. During Iron I, the social structure of the plateau was probably tribal in nature, with loyalties expressed to local families and clans before any larger entity. By the last century of Iron II, however, the copious finds illustrate regional developments in language dialects, writing, and pottery, which more or less correspond to the national boundaries known from the literary evidence. This could only have happened with national unity imposed from strong central governments. A slightly wetter climate may have abetted these processes.

The sites in the Jordan Valley probably belonged to Israel or Judah for the most part. Pella, curiously not mentioned in the Bible, may have been an exception; it may have belonged to Damascus, as did Tel Hadar to the north. [*See* Hadar, Tel.] The best sites for studying the early stages of Iron II were there—such as the walled city of ninth- and eighth-century BCE Saʿidiyeh that contained a small house shrine; a block of relatively poor houses was excavated from the eighth century BCE there, as well. At Deir ʿAlla the inscription of a vision received by the prophet Balaam (*Nu.* 22–24) was found in a layer dated to about 800 BCE. Tell Nimrin has so far produced only a few potsherds from the Early Iron II.

On the plateau, excavations have produced very little from the Early Iron II, except for collared pithoi at Umm el-Hedamus (near Irbid). Surveys, however, have found many sites, including one of the largest tells in Jordan, at Ḥusn and Irbid. Even in the Amman region, sites are few. The Amman citadel has produced potsherds, the ninth-century Amman Citadel Inscription, and a few fragmentary architectural remains have been published, but nothing very coherent has yet emerged. The same is true at Saḥab, ʿUmeiri, and Jawa (South). Jalul (east of Madaba) has, however, produced a monumental flagstone street approaching a gate complex and a tripartite pillared building or a four-room house. The large reservoir at Ḥesban, possibly to be identified with one of the "pools in Heshbon" (*Sg.* 7:4), seems to have been built in this period. East of the Dead Sea, in Moab, excavations at Dhiban (Dibon), although recovering much pottery from Early Iron II, were unable to form a coherent picture of any building. [*See* Dibon.] At Baluʿ, recent excavations have located extremely well-preserved remains from possibly as early as the ninth century BCE, and tombs have been excavated at Madaba and Irbid.

There is much more information for the Late Iron II period, but most of it comes from the plateau, where the number of excavated sites is burgeoning, primarily in the central and southern regions. The Jordan Valley has not been as productive as it was for the earlier periods: its fortunes may have fallen with those of northern Israel near the end of the eighth century BCE. At Saʿidiyeh the domestic quarter with its block of houses continued into the seventh century BCE, but at Deir ʿAlla only a series of pits has been uncovered, and very little beyond a cemetery has been found at Mazar. In the northern plateau, only small deposits with potsherds and fragmentary architecture have appeared at Abila, Fukhar, and Jerash.

In the Amman region many sites are giving a good picture of the late Ammonite kingdom. In the Baqʿah Valley small sites that include towers or agricultural buildings, such as Rujm al-Ḥenu, are scattered across the valley. Overlooking the Baqʿah Valley at Ṣafut, domestic buildings and a large corpus of typical Ammonite pottery has been found. On the Amman citadel many small finds have enriched the period, but the most dramatic remains come from the many tombs and towers/agricultural buildings in the immediate area. South of Amman, at Jawa (South), a structure with two stairways has been excavated within a city fortified with a casemate wall. ʿUmeiri produced a large administrative compound with domestic structures to accommodate the bureaucrats who were administering a royal wine-production facility. Other sites with significant deposits, but less coherent architecture, include Ḥesban, Saḥab, Jalul, ʿIraq el-Amir, and Mt. Nebo. [*See* ʿIraq el-Amir; Nebo, Mount.]

In Moab, Baluʿ has extremely well-preserved houses (several with their corbeled stone roofs still intact). Other excavations have found less coherent remains at Dhiban (Dibon), Umm er-Rasas, Lehun, ʿAroʿer, and Udruḥ, however. [*See* Umm er-Rasas.]

Excavation in Edom has been far more productive than in Moab, primarily because it received more attention from Crystal-M. Bennett's series of early excavations. She uncovered domestic sites on top of Umm el-Biyara in Petra and at Tawilan outside Petra. [*See* Umm el-Biyara; Petra; Tawilan.] She also excavated part of an Assyrian fortress and Edomite structures at Buṣeirah, the capital of Edom. [*See* Buṣeirah.] At the head of the Gulf of ʿAqaba Glueck's excavations at Tell el-Kheleifeh uncovered a trading depot probably associated with Red Sea shipping. [*See* Kheleifeh, Tell el-.] Less significant finds have been made at Petra, Baʿja, Khirbet Dor, Sadeh, Abu Kharaz, Feifa, and Feinan.

The end of the Iron II period is difficult to establish in Transjordan. In the Amman region there is no clear break. Sites like ʿUmeiri, where it has been clearly shown, and Ṣafut, Ḥesban, the Amman citadel, and others seem to extend through the Babylonian period and into the Persian period with no breaks.

Transjordan in the Persian through Roman Periods

Transjordan continued under foreign domination throughout much of the Persian through Roman periods, as the Persians, Ptolemies, Seleucids, and Romans ruled in succession. But this era also witnessed the rise of the Nabateans, one of the most brilliant indigenous civilizations in the history of Transjordan.

Persian Period (539–332 BCE). Little is known about the history of Transjordan in the Persian period. Written evidence is extremely scarce and few excavated sites have yielded material evidence of the period. A few scraps of evidence may be gleaned from the Hebrew Bible, although none can be dated after the mid-fifth century BCE.

Transjordan, Palestine, Syria, and Phoenicia all fell within the Persian province, or satrapy, called "Beyond the River" (i.e., the Euphrates River), possibly based on earlier Assyrian and Babylonian terminology (Olmstead, 1944). The province was governed by a Persian satrap, who in turn supervised territorial subdivisions administered by lesser Persian officials or local notables. Although the names of several such administrative districts are known for Palestine, there is less evidence that the Persians organized Transjordan in such a fashion. They may have installed the Jewish Tobiads to govern Ammon from ʿIraq el-Amir, where two Aramaic inscriptions dated to the fifth or fourth century BCE refer to a member of the Tobiad family. [*See* ʿIraq el-Amir.]

The paucity of written evidence is paralleled by limited material remains from Transjordan. All the regional archaeological surveys report little or no Persian period pottery or any other artifactual evidence from this period. This paucity is in sharp contrast to the preceding Iron II period, which is characterized by numerous occupied sites throughout the region. Some Persian period occupation is attested at a few sites, such as Tell Deir ʿAlla, Tell es-Saʿidiyeh, and Tell el-Mazar in the Jordan Valley. [*See* Deir ʿAlla, Tell; Saʿidiyeh, Tell es-; and Mazar, Tell el-.] Copper mining seems to cease in the Wadi ʿArabah in this period (c. 400 BCE). In addition, the dense concentrations of Iron II sites farther south, in Edom, also were abandoned by about 400 BCE. Thus, it appears that in the Persian period the sedentary population in Transjordan underwent widespread decline and most of the region was outside direct Persian administration.

Certainly the collapse of the Iron Age kingdoms in the sixth century BCE opened the eastern desert frontier to nomadic Arab encroachment. Herodotus (3.88, 91) states that the Arabs were independent of Persian authority, although they did provide logistical support or military contingents to the Persians on occasion, such as for the invasion of Egypt by Cambyses in 525 BCE (Herodotus 2.7–9).

John R. Bartlett (1979) argued for continuity in southern Transjordan from the Iron II Edomites to the Nabateans of the Hellenistic period. However, recent soundings at several Iron II sites failed to demonstrate any continuity of occupation. In Edom, continuity from Iron II into the Persian period has been asserted for such sites as Tawilan and Buṣeirah. Yet, Piotr Bienkowski's (1990) reappraisal of this evidence, including an analysis of the stratigraphic context of a cuneiform tablet that mentions a "King Darius" and a

hoard of Persian jewelry from Tawilan, concludes that this case is unproven. Bienkowski notes that all three of the Edomite sites that have been extensively excavated (Tawilan, Buṣeirah, Umm el-Biyara) were abandoned after fire and/or destruction. [*See* Tawilan; Buṣeirah; Umm el-Biyara.] Whether or not continuity of occupation into the Persian period is accepted, all these sites seem to have been abandoned before the beginning of the Hellenistic period. Finally, Tell el-Kheleifeh, an Iron II stronghold near ʿAqaba, on the Red Sea, also seems to have been permanently abandoned in the Persian period. [*See* Kheleifeh, Tell el-.] Bartlett, modifying his views, now suggests that the Edomites evolved from a sedentary agricultural people to a more pastoral folk (Bartlett, 1990). These people mixed with the newly arrived Nabateans, who were then pastoral nomads who eventually dominated the descendants of the Edomites. (The origins of the Nabateans are shrouded in mystery, but they were present in southern Transjordan by the late fourth century BCE.) It is possible to speculate that the Persian period in Moab evolved in a similar fashion, with the ascendancy of an intrusive nomadic Arab population over the sedentary descendants of the Moabites. These groups probably mingled as the nomads sedentarized. [*See* Edom; Moab.]

Hellenistic Period. Persian rule ended abruptly in 332 BCE, with the conquest of the entire region by Alexander the Great. Alexander, or his immediate successors, such as Perdiccas, may have founded several Macedonian or Greek colonies in the region, although the later sources that assert these foundations may be suspect. After the breakup of Alexander's empire, Transjordan fell to the Ptolemies of Egypt, who ruled until the end of the third century BCE. Little is known of Ptolemaic rule in Transjordan. Ptolemy II Philadelphus (282–246 BCE) refounded Rabbat Ammon (modern Amman) as Philadelphia, but there is only limited archaeological evidence elsewhere of this century, such as at Pella in the Jordan Valley. [*See* Ptolemies.]

The Nabateans were firmly established in southern Transjordan by the end of the fourth century BCE. Stories of their wealth were sufficient to entice a plundering raid by Antigonus the One-Eyed, one of Alexander's former generals, in 312 BCE (Diodorus 19.95). Diodorus, relying on the eyewitness account of Hieronymous of Cardia, describes the Nabateans as completely nomadic and dominating the caravan trade in incense and other luxury products between the Arabian Peninsula and Palestine. The Zenon papyri suggest that the Nabateans were present in northern Transjordan by the mid-third century BCE. By the early second century BCE, if not earlier, the Nabateans were ruled by a monarchy. Their first attested king is Aretas I (c. 170–160 BCE). [*See* Nabateans.]

The conquest of the region by the Seleucids under Antiochus III (200 BCE) seems to have inaugurated a new period of prosperity for Transjordan. Antiochus and his successors fostered the development of several major cities in the north, whether preexisting settlements or new urban foundations. This is suggested by late coins of Pella, Gerasa, Gadara, Abila, and Esbus, which reflect Seleucid dynastic toponyms such as Antioch and Seleucia. Artifactual evidence from these cities suggests commercial contact with major centers of the Hellenistic world, such as Egypt, the Aegean, and Asia Minor. The cultural life of these Greek cities in northern Transjordan must also have been vigorous, as suggested by the several intellectual figures who hailed from them—the satirist Mennipus (third century BCE) and the poet Meleager (c. 140–70 BCE) were both from Gadara. The construction of the Tobiad castle known as Qaṣr el-ʿAbd within an artificial lake at ʿIraq el-Amir is dated to the early second century BCE. [*See* Seleucids.]

The decline and eventual collapse of the Seleucid Empire in the late second and early first centuries BCE brought renewed political turmoil to the region. The resulting power vacuum encouraged the expansion of the Nabateans northward and the Jewish Hasmonean state eastward across the Jordan. Some Greek cities in the north, such as Pella, were destroyed. Most of the others fell under the control of the local dynasts—the Hasmonean or Nabatean. Evidence from Strabo (16.4.21, 26) suggests that the Nabateans had evolved into a largely sedentary people by the first century BCE. This roughly coincides with the earliest evidence for Nabatean sedentary occupation of their capital at Petra, in Edom, which has been dated to the late second or early first century BCE. Caravans hauling frankincense and myrrh traveled north from the Arabian Peninsula, converged on Petra, and then moved west across the Negev desert to Gaza on the Mediterranean or north to Damascus and Syria. A number of Nabatean towns and road stations emerged to service this traffic.

Roman Period (63 BCE–324 CE). The chaos and warfare that plagued much of Transjordan in the Late Hellenistic period ended with the arrival of the Roman general Pompey in 63 BCE. Pompey, who had extinguished the Seleucid dynasty and annexed much of Syria as a Roman province, was content to rule the remainder of Syria, Palestine, and much of Transjordan through a system of native client rulers.

Pompey established the Greek cities as efficient instruments of local Roman administration. Thus, he liberated the ones in northern Transjordan from Jewish and Nabatean control and began their reconstruction. The gratitude of these cities to their liberator is illustrated by their adoption of a new Pompeian era in 64/63 BCE, reflected in their later civic coinage. The Greek cities retained local autonomy but were administratively attached to the Roman province of Syria. There is no evidence that Pompey organized the Greek cities of northern Transjordan and southern Syria into a league or federation called the Decapolis. This Greek term, meaning "ten cities," appears only in first century CE

sources (*Mk.* 5:20, 7:31; Pliny, *Nat. Hist.* 5.74) and refers to an administrative region under a Roman prefect supervised by the governor of Syria (Isaac, 1981). [*See* Decapolis.]

The cities within Transjordan included Gadara (Umm Qeis), Abila (Qweilbeh), Capitolias (Beit Ras), Dium (modern site uncertain), Gerasa (Jerash), Pella (Ṭabaqaṭ Faḥl), Philadelphia (Amman), Esbus (Tell Ḥesban), and Madaba. Each of these cities administered an extensive rural hinterland that formed a largely contiguous territory. The cities formed a distinct Greek cultural unit that distinguished them from the surrounding Semitic regions. The cities developed Greek civic and religious institutions and were laid out on a rectangular grid of streets. All were fortified and acquired many of the accoutrements of typical Roman provincial cities, such as colonnaded streets, classical-style temples, baths, theaters, nymphaeums (fountain houses), and hippodromes (racetracks). [*With the exception of Dium, all of the sites mentioned above are the subject of independent entries.*]

All this public building, most of which was paid for by local benefactors, implies considerable economic prosperity in the Roman period. The basis of much of this prosperity must have been the fertile agricultural hinterland. However, the cities also benefited from the commercial traffic that passed through their territories and from local industries. Hundreds of inscriptions, mostly in Greek, suggest that the urban elite was largely composed of hellenized Semites. The degree to which Hellenism spread to the lower urban classes or to the rural population of their municipal territories is difficult to gauge, but presumably these remained largely Semitic in language and culture. The largely Jewish district of Peraea, located on the east bank of the lower Jordan River north of the Dead Sea, remained part of the client kingdom of Judea (Judah).

The remainder of central and southern Transjordan comprised the heart of the Nabatean kingdom. Recent archaeological surveys have revealed dense Nabatean settlement of the regions east and southeast of the Dead Sea. Many sites are located along the major commercial arteries and presumably benefited from the caravan traffic. A series of small, but splendid Nabatean sanctuaries, such as Khirbet et-Tannur, appeared along these routes. [*See* Tannur, Khirbet et-.] The density of settlement is so great, however, including marginal sites along the eastern desert fringe, that the bulk of the population must have been engaged in agriculture and animal husbandry. Strabo (16.4.24) in fact indicates that by the early first century CE much of the Arabian luxury traffic had already shifted to an alternate route via the Red Sea ports of Egypt, bypassing Nabatea. Hence, some scholars have suggested that the Nabateans were forced by these circumstances to rely increasingly on indigenous resources, such agriculture, animal husbandry, and the mineral resources of the Wadi ʿArabah and the Dead Sea. The Nabateans developed sophisticated hydrological installations at such sites as Avara (Ḥumeima), just north of ʿAqaba, to exploit limited water resources. The sophistication of Nabatean technology is perhaps best reflected in their fine painted pottery. Petra itself apparently reached its peak during the reign of Aretas IV (9 BCE–40 CE). A number of major monuments in the city date to this period, such as the main theater and the temple known as Qaṣr el-Bint. [*See* Ḥumeima; Petra.]

Apart from the various sedentary peoples of Transjordan in the Roman period, there is also exceptional evidence for nomads in the eastern desert, the Safaitic and Thamudic tribes. These Arab nomads were very literate people who left thousands of inscriptions and drawings in the eastern desert. The inscriptions are laconic and difficult to date but suggest that the tribes were camel bedouin who practiced regular patterns of transhumance across the desert frontier. [*See* Safaitic-Thamudic Inscriptions.] The existence of a system of Nabatean fortifications along the desert edge suggests that relations between the then sedentary Nabateans and the nomadic tribes were not always peaceful.

In 106 CE, the Nabatean kingdom was annexed by the Roman emperor Trajan and incorporated into the new province of Arabia, which also included several southern Decapolis cities. The Roman annexation appears to have been peaceful, with little or no resistance from the Nabateans. Bostra (Bosra), a city in southern Syria just north of the modern Jordanian border, became the capital of the new province, which was governed by a senatorial legate appointed by the emperor. The Babatha papyri from caves near the Dead Sea, reveal some details of the Roman administrative organization (Naphtali, 1989). Trajan built a major highway, the Via Nova Traiana ("Trajan's new road") that extended from Bostra in the north to Aila (ʿAqaba) on the Red Sea in the south. The Nabatean army was incorporated into the Roman army and transferred out of the province. It was replaced by a sizable Roman force, led by the Third Cyrenaica Legion based at Bostra, and a number of auxiliary units. Latin inscriptions on milestones attest the construction and periodic repair of both Trajan's road and several other provincial roads throughout the Roman period. [*See* Bosra; ʿAqaba.]

The economic prosperity enjoyed by Transjordan continued under Roman rule through the second and into the third centuries CE. A number of cities embarked on major public works programs, most funded by local elites but others by imperial patronage. An example of the latter is the emperor Hadrian, who spent the winter of 129–130 at Gerasa. Most of the cities began to mint their own bronze coinage and some received honorific titles, such as *colonia*.

Transjordan did not escape the general turmoil that struck the Roman Empire in the mid-third century. The great Sasanian Persian invasions of the Roman East (c. 260 CE) did not reach this far south, but the meteoric rise of Palmyra, in

Syria, resulted in the defeat of the provincial Roman army and the Palmyrene occupation of Arabia. Nomadic Arab tribes apparently exploited Roman weakness and increased their pressure on the desert frontier.

The emperor Diocletian (284–305) reunified the empire and began a massive military buildup along the desert frontier in Transjordan. He constructed many new fortifications, deployed new military forces, and systematically repaired the provincial road system to facilitate military traffic. The most important Diocletianic military foundation was the legionary fortress at Betthorus (el-Lejjun), east of the Dead Sea, which housed the Fourth Mars Legion. This fortified frontier, known as the *limes Arabicus,* was intended to control the raids of nomadic Arab tribes. [*See* Lejjun; Limes Arabicus.] Diocletian also reorganized the provincial administration by partitioning the old Trajanic province of Arabia. Transjordan south of the Dead Sea and east of Wadi 'Arabah was transferred to the province of Palestine. The region east of the Jordan River and the Dead Sea remained a truncated province of Arabia. The success of Diocletian's policies in restoring a large measure of security and prosperity to the region is reflected in the dense pattern of settlement revealed by various regional surveys and by programs of church construction in the succeeding Byzantine period.

Transjordan in the Byzantine Period

The period between the reign of the emperor Constantine (332 CE) and the Muslim conquest in the mid-seventh century CE is identified in the history of the Near East as Byzantine, and as Late Roman in other geographic regions. The nomenclature *Byzantine* derives from the capital city of the Eastern Roman Empire, Byzantium/Constantinople (modern Istanbul), which exerted control over all of the eastern Mediterranean basin. Because the initial impetus for archaeological research throughout the Near East was the explication of the biblical milieu, the Byzantine period was neglected by early archaeologists. The study of the period fell within the purview of scholars dealing with religious or art history, whose primary concern was monumental remains. Within the last thirty years, the continuity of human occupation from the Roman to the Islamic period has been researched stratigraphically and with a growing emphasis on social history.

As early as the 1920s, the perspective of archaeological research in Jordan was broad: excavations were being conducted on the Amman citadel (Roman/Byzantine Philadelphia; modern Amman) and at Gerasa/modern Jerash. Neither site has been continuously excavated, however, because they have been continuously inhabited. In Jordan, it is almost axiomatic that "some Byzantine" will be found in excavation. A further impetus to understanding the period came with the research conducted on the material culture from Pella (Smith, 1973) and Hesban (Sauer, 1973).

Sites. Byzantine-period sites have been identified in every topographic and environmental zone, although site types are diverse: encampments and farmsteads, particularly along fertile *wudyan* ("valleys"); industrial areas, including wine and olive presses, located between urban areas); fortlike installations, often reused from earlier periods, such as those surrounding Amman (see below); military installations, such as those along the limes Arabicus; villages; towns; cities; and monastic complexes. As archaeological techniques have developed, so has the ability to identify sites and interpret their interrelationships. Modern surveys, as well as the contributions from nineteenth- and early twentieth-century explorers, travelers, and archaeologists, indicate a landscape with a flourishing Byzantine settlement pattern in which the cities were interdependent with the hinterland in a local and regional network.

Among the most significant Byzantine sites are those identified as the Decapolis cities, although the Hellenistic and Early Roman administrative understanding of the identification did not have the same meaning. Six of the Decapolis cities were located on the border of northwestern Transjordan, in the Byzantine province of Palaestina Secunda: Amman/Philadelphia and Beit Ras/Capitolias (at various times within the boundaries of the Provincia Arabia); Umm Qeis/Gadara, Wadi Qweilbeh/Abila, Ṭabaqaṭ Faḥl/Pella, and Jerash/Gerasa. These cities, excluding Beit Ras/Captiolias, were all earlier tell sites. All of these sites have been excavated to varying degrees. [*See* Decapolis.]

During the Roman period, earlier aspects of cities were incorporated into a stone-built urban environment, modified and expanded from the Hellenistic concept. The configuration of the cities included gates, walls, *cardini,* and *decumanii,* forming insulae delineating public and private spaces. Public space consisted of a forum, theater, odeum, nymphaeum, temple, hippodrome, or bath, with the largest of the cities having multiple facilities. Outside of the city limits, there were extensive necropoli. The urban environment required intricate water and sewage systems, as seen in the remnants of aqueduct systems at Gadara, Capitolias, Abila and other sites throughout the country. [*See* Aqueducts; Baths; Odeum; Theaters.]

The population reused this architectural environment by modifying it. The theaters and odea, at Ṭabaqaṭ Faḥl/Pella, for example, were altered to meet other needs. As the population converted to Christianity, earlier temples and synagogues were reconfigured into churches, such as at Gerasa. The replacement of the central Roman authority of the polis system and the divisions within the Christian community contributed to the transformation of the cities: as authority rested with church hierarchies, public space was used to accommodate the construction of churches and to provide market space.

It is the tessellated (mosaic) pavements within several excavated churches that have so interested Byzantine art and religious historians. The most famous is the Madaba mosaic map, dated to about 560 CE, which depicts holy sites from the Bible and the area's major geographic features, among them the Jordan River, the Dead Sea, and the Nile Delta. The map is located in the modern Church of St. George in Madaba, only one of several Byzantine-period tessellated pavements found in the town. These pavements and those from surrounding sites—Maʿin, Umm er-Rasas (ancient Kastron Mefaa), Mt. Nebo (the place identified by the Byzantines as where Moses is purported to have looked across the Jordan River), Mukhayyat, and ʿAin Mousa—indicate the wealth of parts of the Byzantine community, give the names of officials (ecclesiastical and municipal), and attest to the continuance of the community following Muslim hegemony. Although Madaba-region pavements are the best known, there are others of equal importance from other cities—from Petra and such outlying areas as Riḥab, Khirbet el-Burz, and Khirbet es-Samra. [*See* Mosaics; Madaba.]

The Jordanian "hauran," or steppic sites (Umm el-Jimal, Umm as-Surab, Dayr al-Qaf, Dayr al-Qinn) experienced extensive Byzantine occupation. They differ from the inland urban areas in the following ways: architectural style (their affinities are more to southern Arabia); building techniques (which varied with the use of the indigenous basalt); a lack of a systematic insulae system of spatial arrangement; and a waste system that was not the intricate, below-the-street, stone sewage system of other sites. As at the inland sites, churches proliferated. At some desert sites (e.g., Azraq, Qaṣr al-Ḥallabat) there are indications of occupation earlier than the Islamic period. They, as well as sites to the south and along the Dead Sea (e.g., the Byzantine monastic complex at Deir ʿAin ʿAbaṭa, the Church of St. Lot), show intricate water systems both within the inhabited areas (cisterns) and in the surrounding fields (irrigation channels). [*See* Irrigation.]

Material Culture. During the approximately three hundred years of the Byzantine period, its material culture exhibits only gradual changes. Regional studies—that is, comparisons of corpora from two provinces or from linked cities (e.g., the *trichora* cities, Jerash/Gerasa, Ṭabaqaṭ Faḥl/Pella, and Beth-Shean/Scythopolis)—are of recent design, as are studies of particular types of material culture as indicators of custom, trade networks, manufacturing, and social stratification.

Architectural innovation in the period was related to the development of the church and its decoration. This innovation appears in arches, apses, domes, and roofing techniques. It appears that the Byzantines altered their building techniques to strengthen them to meet natural disasters, such as earthquakes. They used different-sized ashlar blocks, shortened the spans of arches, and used a mortar tension-reducing system. Churches, public buildings, elite private residences, and tombs were decorated with patterned tessellated pavements in which classical themes or the natural world were recreated both on floors and walls; intricately carved and inscribed stone (imported marble and local stone) with floral or religious motifs; and painted plaster and frescoes. The painted tombs at Abila attest to the wealth of some in the Byzantine community there, as well as to a commonality in the use of artistic themes and iconography with other parts of the Byzantine world. As a result of protection by the government of Jordan, the emphasis in research at these sites has been on their monumental remains, except at Pella and Gerasa, where the researchers have investigated the two cities' domestic sectors (see Smith, 1973; Zayadine, 1986).

The pottery from Byzantine sites both varies from site to site and is consistent with types from other regions. The consistency has permitted detailed studies of trade patterns, once clay sources and manufacturing centers have been identified (Sauer, 1973). All methods of manufacture were employed: hand, slab, coil, slow-wheel, fast-wheel, and molding, as well as in combination. The pottery is generally kiln fired rather than reduction fired. Surface treatments vary: incising, combing, painting, washes, slips, ribbing, or ridges. Frequent imports are the so-called Late Roman slipped fine wares, "Late Roman C" apparently being the most frequent. There is evidence of local imitations of the forms; however, no local kilns have yet been excavated. Decoration reflected the population's new religious affiliation: crosses and other images associated with Christianity (fish) are represented. Fine-ware bowl forms identified in the Galilee region are also found in northern Transjordan. Amphorae were shortened and took on a more squat appearance throughout the empire. Forms from the coastal area of Palaestina Prima (the Gaza jar) are found infrequently. Ubiquitious in northwestern Transjordan and in the Hauran, but less frequent south of Amman, is the biansulate red- or dark-ware amphora/jar first published by Smith (1973). It was reduction fired and the body was painted with circular loop designs. The form is an excellent chronological indicator, for most sites in Palestina Prima, when associated with clear stratigraphic layers—particularly because it has been shown that the form continues well into the Islamic period (Walmsley, 1987). Lamps were molded and are consistent with corpora to the west, with the "candlestick" form being the most frequent. A unique lamp form is the "Jerash lamp," identified as originating from Jerash by inscriptions from Early Umayyad examples, not by kiln evidence. Although "slipper" shaped, it has a high, pinched handle in a stylized zoomorphic form. Basin forms of varying sizes, lanterns, and types of candelabra have been reported from other areas, but infrequently.

Metal and glass are less often found preserved at archaeological excavations. Researchers have reported finding iron tools (blacksmith and carpenter), several types of iron nails used on roof and coffin construction, decorative metal, other metal implements (the latter are the least numerous), and copper basins and bowls. Glass remains consist of tesserae, cups, beakers, bowls, and bowl lamps from chandeliers.

Numismatic data have not been collated by site and mint for recent archaeological excavations. (The best data for these remains are to be found in individual site reports.) Because of the continuity of habitation at several ancient urban sites to the present, hoards and/or in situ coin corpora are uncommon.

Conclusion. During the Byzantine period, Jordan was intensely settled. By synthesizing the data from nineteenth- to early twentieth-century researchers with the results of recent work, it is possible to describe the nature of settlement in detail. It was the advent of Christianity, the gradual conversion of the population, and the alterations to the administrative structure of the region that precipitated changes in the material culture, in architecture, pottery, glass, and coins. Despite the fact that there has been a marked increase in archaeological research for the Byzantine period in Transjordan, it is only within the last decade that social history—with all its concommitant refinements of interpretation—has become a priority. It will take several years, however, before new synthetic analyses that include the church/monastic hierarchy, and all associated materials can be formulated and compared with those belonging to the urban and hinterland settlements. When such studies take place, Byzantine studies in Transjordan will have come of age.

Transjordan in the Islamic Period

Islam and the Byzantine world first confronted each other directly in Transjordan in a skirmish at Mu'ta, south of Kerak (al-Karak), in 629, during the lifetime of the prophet Muhammad. Over the next decade, Muslim raids deep into Transjordan and Palestine led to repeated defeats of the Byzantines, already exhausted by a disastrous war with Sasanian Iran that had only ended in 628. Muslim victories at Ajnadayn, al-Fihl (Pella), and Yarmuk overwhelmed the Byzantines, leading to the fall of Damascus in 635, of Jerusalem in 638, and the withdrawal of the Byzantine army from Syria. [*See* Sasanians; Pella.]

In 638, the second caliph, 'Umar al-Khattab, traveled from Medina through Transjordan to accept the surrender of Jerusalem from its patriarch, Sophronius. 'Umar also traveled to al-Jabiya in the Jawlan to organize the government of Greater Syria, creating the system of *junds* ("military districts") that survived as administrative units until the Crusades in the eleventh century. Much of Transjordan and northern Palestine henceforth constituted the *jund* of al-Urdunn.

In 661 Mu'awiyah became the first Umayyad caliph, and with his accession, Damascus became the capital of the Islamic state. Amman (Byzantine Philadelphia) became Transjordan's main administrative town, with its governor's palace within the walls of the Roman citadel overlooking the city. [*See* Amman.] Although built in the local stone tradition, the palace's four iwans and their decoration reflect Sasanian models, part of the eclectic character of Early Islamic art and architecture.

Transjordanian villages in the Balqa' and the Hauran, which generally had been occupied since at least Nabatean and Roman times, continued to be settled under the Umayyads with little if any sign of disruption or destruction. [*See* Nabateans.] This continuity is especially marked in ceramics, with late Byzantine pottery indistinguishable from the earliest Islamic pottery until a distinctive Umayyad pottery emerged. Many places settled before the advent of Islam remained settled throughout the Early Islamic period. Much of the population probably remained Christian, but the presence of Muslims in this period is marked by the conversion of churches into mosques (e.g., Umm el-Jimal)—although at some places, such as Umm al-Walid, Qastal, and Jerash, new mosques were built to meet the needs of the Muslim community. [*See* Churches; Mosques; Umm el-Jimal; Jerash.]

The tribes of Transjordan and Syria were a mainstay of the Umayyad regime, providing military forces that helped sustain the vast territory of the Umayyad caliphate. Mu'awiyah had already resorted to the desert margins near Amman and, in time, the Umayyads' predilection for the region and their reliance on tribal support from those eastern areas of Transjordan were reflected in their intensive building in the region, with major palatial structures at Qastal, Quṣayr 'Amra, Qaṣr al-Ḥallabat, Qaṣr al-Meshatta and Qaṣr al-Tuba. [*See* Quṣayr 'Amra; Qaṣr al-Ḥallabat; Qaṣr al-Meshatta.]

Routes from Damascus, Jerusalem and Egypt to Medina and Mecca all pass through Transjordan, following the ancient Arabian caravan road that was adopted by the Islamic *hajj* ("pilgrimage"). The roads to the Hijaz from Egypt and southern Palestine also passed through al-'Aqaba, a major site founded in the Early Islamic period. [*See* 'Aqaba.]

With the overthrow of the Umayyads in 750 by the 'Abbasids, Greater Syria became a backwater. Instead, the 'Abbasids' new capital, Baghdad (founded in 762), attracted population and wealth; the 'Abbasids tended to avoid Transjordan and Syria, marked as they were by pro-Umayyad sympathies. The Umayyads' palatial foundations in the marginal lands of Transjordan fell into disuse, and only old, established settlements farther west (e.g., Amman, Pella, Jerash) seem to have continued to be settled. The continuity of town and village life in western Transjordan and Palestine emerges in the descriptions provided by the tenth-century geographer al-Maqdisi.

In the course of the ninth century, the 'Abbasids' grip on central government deteriorated and the southern regions of Syria passed under the Tulunids, the 'Abbasids' governors in Egypt. However, by the late ninth century, the authority of the Tulunids became more tenuous. Transjordan suffered raids by the North Arabian Bani Tayy', who pushed the established local tribes westward, depriving them of land they had held since Byzantine times. The Tayy' so disrupted Transjordan that the later Tulunids were no longer able to guarantee the annual Damascus pilgrimage caravan.

The Jarrahid clan emerged as the dominant tribal group among the Bani Tayyi', briefly ruling from Ramla—although they were an unstable political presence. [*See* Ramla.] After the establishment of the Fatimid caliphate in Egypt in 969, the Jarrahids attempted to maintain relations with both Cairo and the Byzantines in northern Syria. In the end, however, southern Syria came under Fatimid domination.

The tenth–eleventh centuries lack clarity in Syria in general, although excavations at Amman show that the citadel remained occupied. The Byzantines threatened northern and central Syria, while the Fatimids dominated the south.

In the latter decades of the eleventh century, the westward advances of the Seljuk Turks and Turkoman tribes led to the diminution of Fatimid power in Syria; the Byzantine presence collapsed after their defeat at Manzikert in eastern Anatolia in 1071.

The coming of the Crusades in 1099 created an entirely different political framework, and new states were carved out on the coast. The southernmost Crusader state, the Kingdom of Jerusalem, bordered an isolated Fatimid Egypt in the south, with its eastern border on or beyond the Jordan River. Among the effects of the Crusades was the rapid development of military architecture, well demonstrated in Transjordan at Shawbak and Kerak. In the Islamic world the military emerged as the leading group in society, reflected in the rise of the *mamluks* (military slaves), who emerged as patrons of the luxury crafts.

From the first, the Crusaders pursued an aggressive policy in Transjordan. In 1110 they raided Petra, where they encountered a community of Christian monks, and in 1121 they attacked Jawlan, took Jerash, and carried off Arab herdsmen's flocks in the Hauran. [*See* Petra.] Perceiving a vacuum southeast of the Dead Sea, in about 1115 they built the fortress of Krak de Montreal at Shawbak to protect the southern approaches to Palestine. Other fortresses were built at ʿAqaba and on the offshore island of Graye (Jazirat al-Fara'un). In line with the same strategy, fortresses were built at Wuʿaira in the Petra valley and at al-Kerak (Petra Deserti), the old Byzantine Charachmoba. The latter was the greatest of these, built in 1142 by Pagan the Butler; it was the lynchpin of the Crusader presence in Transjordan. [*See* Kerak.]

After the initial blow of the Crusader invasion of the Near East, the Muslim counterattack took time to develop; however, the Zangid rulers of Mosul fought back, taking Edessa in 1144. In 1154 the Zangid sultan Nur al-Din took Damascus, creating a unified Islamic state that ran along the Crusaders' eastern frontier. Nur al-Din then projected his power southward, through Transjordan to the Hijaz and toward the rich prize of Egypt, then weakly ruled by the Fatimids. A Zangid expedition finally brought the Fatimid caliphate to an end in 1171. Nur al-Din's officer, Salah ad-Din al-Ayyubi (Saladin), emerged first as the dominant figure in Egypt and then, with Nur al-Din's death in 1174, as Nur al-Din's successor in Syria as well, founding the Ayyubid regime. With Egypt and Syria eventually unified under him, Salah ad-Din prosecuted the war with the Crusaders. However, in the early years of his rule, the Crusader presence in Transjordan, especially at al-Kerak, severely threatened Ayyubid communication among Egypt, Syria, and the Hijaz.

Muslim caravans from Syria to the Hijaz were forced eastward for security reasons, passing through Transjordan via Burquʿ and Azraq along Wadi es-Sirḥan into northern Arabia. [*See* Azraq.] Nur al-Din's general, Shirkuh, went on pilgrimage along this easterly route in AH 555/1160 CE, rather than risk Crusader attack. In the south, the route from Cairo through Sinai to ʿAqaba was similarly imperiled. [*See* Cairo; Sinai.] As to the land route between Damascus and Cairo, only heavily armed bands could risk marching to Egypt through the Transjordanian desert, using remote wells like those at Jafr.

Under the imaginative and unscrupulous Reginald de Chatillon, al-Karak became a base for raids deep into northern Arabia; he built boats on the Dead Sea that were carried to ʿAqaba in order to raid Islamic ships and towns along the Red Sea. Those sorties threatened not only the holy cities, but the Egyptian economy as well.

The situation was completely transformed in 1187, when Salah ad-Din's army defeated the Crusader army at Hattin in northern Palestine, capturing the king of Jerusalem and most of the Crusader leadership. After this massive victory, Jerusalem and most of Palestine were at last regained by the Muslims. The Crusaders were confined to the Mediterranean coast, having lost Kerak and the rest of the fortification system in Transjordan and Syria to the Ayyubids. Although the Crusaders had been driven out of Transjordan, military considerations remained paramount. The Ayyubid sultan of Damascus, al-Malik al ʿAdil (1196–1218), built a new fortress at ʿAjlun; in 1237, ʿIzz al-Din Aybak, on behalf of the Ayyubid sultan of Damascus, al-Malik al-Muʿazzam, rebuilt the Roman fort at Azraq, the main fortress controlling traffic from Wadi es-Sirḥan to Transjordan. [*See* ʿAjlun.]

After the death of Salah ad-Din in 1193, the Ayyubid territories began to be divided among his family—although the family retained a degree of unity. In 1250, the last Ayyubid sultan in Egypt was overthrown by *mamluks*, while independent Ayyubid princes continued to rule in Syria and Transjordan. In 1260, a pagan Mongol army invaded Syria after sacking Baghdad and killing the ʿAbbasid caliph. [*See* Baghdad.] They reached as far as northern Palestine, where the Egyptian *mamluks* defeated them near Nazareth. [*See* Nazareth.] In the aftermath of the battle, a *mamluk* general, Baybars I, emerged as sultan, ruling both Egypt and the ravaged territories of Syria.

Al-Karak remained under an Ayyubid prince, al-Mughith ʿUmar, until he was taken and killed by Baybars in 1263. Kerak became one of the "kingdoms" of Syria, ruling much of Transjordan; however, it was the second city of the sultanate and lower in status than Damascus.

The remoteness of Kerak made it a useful retreat for the insecure, the dissident, and the rebellious. Thus, Sultan Nasir Muhammad ibn Qala'un abandoned Cairo in 1309 to evade the growing power of his great amirs. Ostensibly, he was to make the pilgrimage, but instead he stopped in Transjordan, establishing himself at al-Karak with his own *mamluks*. He recruited an Arab tribal army, with which he returned to Cairo. He executed his overbearing amirs and regained the sultanate. In 1389, Sultan Barquq did much the

same: he went from Cairo into exile in Kerak in 1389, where he found support and subsequently recovered the throne in Cairo.

Palestine and Transjordan were spared the Mongol attacks of the late thirteenth century, while on the Mediterranean coast, the Mamluks took the last Crusader strongholds by 1291. Many areas of Transjordan saw a revival for the first time since the Umayyad period. In the Hauran, Balqa', Moab, and Edom, archaeological evidence suggests a revival of settled life. [*See* Moab; Edom.] In the Jordan Valley and southern Ghor there also is evidence of a sugar industry in Ottoman times whose origins may go back to the Mamluk period. [*See* Jordan Valley.] In the remote mountains flanking Wadi ʿArabah, the ancient copper mines were reworked under the Mamluks.

In the early sixteenth Century, the threat by the Portuguese to Red Sea shipping led the Mamluks to cooperate with the rising Ottoman power in Istanbul/Constantinople. [*See* Constantinople.] Coastal defenses were improved and a new fort was built at ʿAqaba by the Mamluk sultan al-Ghawri. However, in 1516 al-Ghawri was defeated by the Ottomans in northern Syria; the following year, Cairo fell, the Mamluk sultanate ended, and the Ottomans emerged as rulers of the entire Near East.

In Transjordan under the Ottomans, the traditional interest of Muslim rulers in secure passage for pilgrimage continued. A series of fortifications was constructed along the pilgrim road from Damascus to the Hijaz on the orders of Süleiman II and his successors: at al-Qutrana, Dhat al-Hajj (1554), and Qal'at el-Hasa. They remained a means of exercising control over these more remote areas until the Hijaz Railway made them redundant.

TRANSPORTATION. From the earliest periods of recorded history in the ancient Near East, land transportation is well attested. It appears to have played a major role both in the region's history and in its sociological and technological development. The frequency of travel and transportation is recorded in all periods in written records. It is generally motivated by the same activities that involve people everywhere: commuting to work, visiting friends and relatives, attending religious festivals; buying and selling goods; and attending weddings, funerals, banquets, and the like.

Three categories of travel were especially significant in the ancient Near East. The first is that of traders. The need to transport goods and materials from region to region influenced, more than any other single factor, the development of an intricate system of roads and highways spanning the Fertile Crescent. Trade was also responsible for the region's cultural cross-pollination, a phenomenon of great social and historical import.

A second significant category of travel is that of the messengers who functioned as the postal service. Messengers linked the various cultures of the Fertile Crescent in active communication, profoundly influencing the region's history. From the early Sumerian period onward, royal, civil, and private messenger services flourished. The widespread activity of messengers is attested, for example, by the 379 Amarna tablets of the second millennium BCE, which represent vigorous correspondence between Egypt and the rest of the Near East. Later, imperial Persian messengers covered the Royal Road from Persepolis to Sardis (about 2510 km, or 306 mi.) in nine days, averaging about 275 km (171 mi.) a day. This efficient postal service was set up somewhat like the Pony Express in frontier and colonial America whose posting stations were about 24 km (15 mi.) apart and supplied fresh horses and riders. During the Roman period the extensive *cursus publicus,* the state postal and messenger service, included regular stops along the main highways where horses could be changed; larger stations and inns were established about one day's journey (37 km, or 23 mi.) apart.

The movement of armies constitutes the third significant category of travel and transportation, accounting for a large percentage of the activity along the thoroughfares of the ancient world. Those armies of course also accounted for many notable historical developments in the region.

The primary mode of travel throughout the ancient Near East was by foot. Even government officials normally trav-

eled that way. Travel by donkey was generally reserved for women, children, and the infirm. Riding the mule, horse, and camel is almost unattested until the first millennium BCE, and even then it remained relatively uncommon.

The light horse-drawn chariot appeared early in the second millennium BCE as a means of transportation and quickly became an invaluable military vehicle. The chariot continued in use during the Roman period, when the carriage became more popular. One type of the latter, the *verreda,* was drawn by four mules and could transport two or three people. A two-wheeled *birota,* on the other hand, had three mules and carried one or two passengers.

The transportation of goods and materials of considerable size and weight was generally by means of donkeys, carts, and wagons. The most common means of land transportation, attested as early as the fourth millennium BCE, was the donkey, an animal able to move easily along steep and stony mountain paths difficult for wheeled vehicles and uncomfortable or dangerous for camels. Caravans of donkeys are frequently mentioned in the Old Assyrian and Old Babylonian periods and throughout the second and first millennia BCE. The use of other animals—the mule, ox, and camel—in transporting goods was far less common. The camel, which came into more general use at the very end of the second millennium BCE, had the advantage of being able to carry about five times the capacity of the donkey and could travel for extended periods of time without water, making it especially valuable for desert transportation.

Wheeled vehicles apparently originated in Sumer during the early third millennium BCE. The earliest type was a heavy four-wheeled, ox-drawn wagon, from which the two-wheeled cart developed—a lighter vehicle that could be drawn by horses or mules. Clay models of covered wagons have been found in Sumerian sites from as early as 2500 BCE, and wagons and carts frequently appear in both the written records and the art of the entire region. Carts and wagons were especially useful for transporting heavy loads, such as large quantities of metal, timber, and military supplies. During the Roman period the most common means of land transportation was the ox-drawn wagon, normally pulled by eight oxen or horses in the summer and ten in the winter. Heavy goods, such as army supplies, were all transported by even larger wagons, called *clabulariae,* which could carry as much as 1,500 Roman pounds. Express goods were carried by the swifter *cursus velox,* which employed several types of lighter carriages.

DAVID A. DORSEY

TUFNELL, OLGA (1904–1985), English archaeologist. In 1922 Tufnell worked as a secretary in London for W. M. Flinders Petrie. In 1927 she joined Petrie's team in Egypt and then his expedition in southern Palestine, first at Tell el-Far'ah (South) and then at Tell el-'Ajjul. Not having studied archaeology formally, she gained experience, knowledge, and training at those excavations, working with Petrie and his assistants, principally James L. Starkey. [*See* Far'ah, Tell el- (South); 'Ajjul, Tell el-; *and the biographies of Petrie and Starkey.*]

In 1932, following a rift with Petrie's wife, who had an active role in the management of the Tell el-'Ajjul expedition, Starkey decided to open his own large-scale excavations at Tel Lachish (Tell ed-Duweir). A number of Petrie's assistants, primarily G. Lankester Harding and Tufnell, went with him. The excavation at Lachish lasted for six seasons, coming to an abrupt end when Starkey was murdered by Arab bandits in January 1938. [*See* Lachish; *and the biography of Harding.*]

Tufnell returned to England, where she dedicated herself to the monumental task of publishing the results of the Lachish excavations, a project that took about twenty years (with an interval during World War II). *Lachish II,* on the Canaanite fosse temple, appeared in 1940; *Lachish III,* which reported on the Iron Age remains, appeared in 1953; and *Lachish IV,* the Bronze Age finds, appeared in 1958. Tufnell also wrote a number of papers on other subjects. In 1984, shortly before her death, she published a detailed book on the scarabs of the early second millennium BCE.

Tufnell's main contribution to the Lachish excavations was the registration, classification, and study of the finds. Her publication of the Lachish pottery and her typological

divisions are excellent and most useful in modern terms. She made penetrating observations, especially remarkable because she lacked formal training in ceramics. Her most important observations regarding Lachish, were not accepted at the time by the scholarly world but have since been proved correct by subsequent excavations at the site. Her assessment that the last Canaanite city (level VI) was not destroyed until after the reign of Pharaoh Rameses III (twelfth century BCE) and that level III was destroyed in 701 BCE by Sennacherib, king of Assyria, has been confirmed.

In addition to her devotion to archaeology, Tufnell is remembered as a modest and kind person. During her stay at various excavations, she served both as archaeologist and nurse, providing medical help from an expedition's dispensary to local Arab villagers.

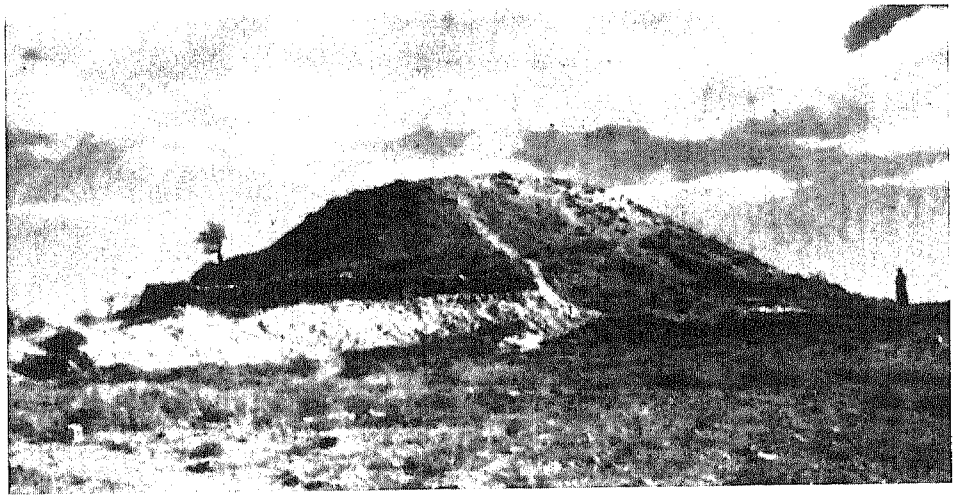
DAVID USSISHKIN

TUMULUS. An artificial mound of stones and/or earth (the term *cairn* is sometimes used interchangeably), a tumulus (Ar., *rujm;* Heb., *rogem*) most often covers a burial cist or chamber. Tumuli are found throughout the Near East and beyond. They tend to be located in ecological zones (steppe, hilly maquis, and desert) more amenable to pastoralism than field-crop agriculture, such as in the Negev desert, on the Transjordan plateau, in the central and Carmel highlands of Israel, and on the Syrian steppe.

Tumuli are variously constructed: the most common form is a stone circumference filled with stone and earth to form either a conical mound or a flat-topped, drum-shaped structure. A burial chamber constructed with upright slabs or stone courses or sunk as a cist, usually occupies the center. The chamber's roof—generally of slabs—can be either covered by the tumulus or flush with its top. Dolmens were always covered by tumuli. [*See* Dolmen.] Monumental tumuli, such as the mysterious Iron Age group in the Jerusalem area and Rujm el-Hiri on the Golan Heights, comprise another type. Tumuli are often associated with other features, such as enigmatic, single or double rows of stones, and cupmarks and altars, all of which imply symbolic/cultic behavior.

Like the dolmens, the floruit of the tumulus phenomenon in the Levant seems to occur in the Early Bronze and Intermediate Bronze Ages, although earlier origins are possible and later use is documented. The Baghouz tumuli near Mari in Syria date to the Middle Bronze Age, and the great tumulus fields of Bahrain (ancient Dilmun) appeared in the third millennium and remained in use until the Early Islamic period (seventh–eighth centuries CE). Of all the tumuli in the ancient Near East, those of Phrygia, in Asia Minor, dated to the Archaic period (first half of the second millennium BCE), were the wealthiest and the most monumental. [*See* Gordion.]

Tumuli functioned primarily as burial structures. Most tumuli fields include at least a few that contain human skeletal material. Mordechai Haiman (1992) has suggested that fields containing larger tumuli not closely associated with settlements are also the locus of a mortuary cult. Like dolmens, tumuli fields may also mark territorial boundaries.



TUMULUS. *One of the great tumuli in the Jerusalem area.* Dated to the Iron Age II period, c. eighth century BCE. (Courtesy D. Ilan)

Particularly large tumuli, such as Rujm el-Hiri, the Iron Age tumuli around Jerusalem, and those of Phrygia most certainly functioned as symbols of power and the sites of an elite mortuary cult.

TURKEY. *See* Anatolia.

TURVILLE-PETRE, FRANCIS (1901–1942), prehistorian and archaeologist. Born in Great Britain and educated at Oxford University under the supervision of R. R. Marett, Turville-Petre joined the British School of Archaeology in Jerusalem after graduating from Oxford, arriving in Palestine in 1923. He surveyed along Naḥal ʿAmud in the eastern Galilee and in 1925–1926 excavated the Emireh and Zuttiyeh caves under the auspices of the British School. He published a full account of his excavations in 1927. His conclusions concerning the transitional character of the lithic industry from the main layer of the Emireh cave were later confirmed when Dorothy A. E. Garrod identified the Emireh assemblage, which she named Emiran, as the industry marking the transition from the Mousterian to the Upper Paleolithic. The assemblage contained few blades, numerous flakes including Levallois points, and among the retouched points were end-scrapers and some burins. Turville-Petre's discovery of a fragmentary skull at Zuttiyeh, which is one of the earliest human fossil remains ever found in the region, brought him instant fame. Later testing confirmed that the skull is related to the Acheuleo-Yabrudian culture, currently dated as more than 250,000 years old.

Turville-Petre spent 1929–1930 in Berlin for medical treatment. In 1930, he conducted a survey and excavation of a field of dolmens east of Korazim, near ʿAmiʿad in the eastern Galilee. In 1931, following an invitation from Garrod, he excavated in the Kebara cave in the Carmel range, where he uncovered Natufian, Kebaran, and Levantine Aurignacian layers. He described the finds from the first two in a preliminary report (the last was studied by Garrod). He also tested the Mousterian deposits but did not report his results. From 1933 to 1941, Turville-Petre lived mainly in Berlin; he later settled in Greece, on St. Nicholas Island. In the wake of the 1941 German invasion of Greece, Turville-Petre was evacuated to Cairo, where he died the following year.

OFER BAR-YOSEF

TYANA, classical city located on the southeastern Anatolian plateau, and its surrounding region, the *Tyanitis,* on the north side of the Toros-Bolkar Mountains and to the west of the Ala Mountains. Tyana controlled the north end of the Cilician Gates, which open the way between these mountains down into Cilicia. The ancient city was located beneath the modern town of Kemerhisar, some 20 km (12 mi.) southwest of Niğde, following the discovery of classical inscriptions on the *höyük,* or city mound. The area was surveyed by a Turkish archaeological team in the 1980s but has not been excavated. The Roman aqueducts that led to the site are still visible. Iron Age sites (principally Zeyve Höyük and Tepebağlari, and Göllüdağ) probably belonging to the kingdom have been excavated but are poorly reported.

An earlier form of the name Tyana is identified in that of the city of Tuwanuwa, attested in the cuneiform Hittite texts of the Ḫattuša archives (c. 1650–1200 BCE). A bridge between the two names is provided by a stela with a hieroglyphic Luwian inscription found at Bor, near Kemerhisar, that names Warpalawa (c. 740–705 BCE), a local king of the city Tuwana, in the Neo-Hittite period (see below).

The cuneiform Hittite references show that the city of Tuwanuwa was incorporated into the Hittite kingdom at its

inception (Edict of Telipinu, 4; *Keilschrifttexte aus Boğazköy* [*KBo*] vol. 3, text 1, col. 1, l. 10; *Kielschrift urkunden aus Boğazköy* [*KUB*], vol. 11, text 1, col. 1, l. 9; *KBo*, vol. 3, text 67, col. 1, l. 9), but that it frequently fell into enemy hands (Decree concerning *hekur Pirwa*, *KBo*, vol. 6, text 28 obverse l. 9; Deeds of Šuppiluliuma, *KBo*, vol. 14, text 3, col. 4, ll. 21, 40, 42, and *KUB*, vol. 19, text 18, col. 1, ll. 16, 17; see Hans Güterbock, *Journal of Cuneiform Studies* 10 (1956), 76 ff.). Some towns of Tuwanuwa were included in the Sahurunuwa Donation (*KUB*, vol. 26, text 43 obverse l. 38). The town and its gods remained important in the Hittite cult: they are mentioned in the Muršili Plague Prayer (*KUB*, vol. 6, text 45, col. 2, l. 18 ff.; text 46, col. 2, l. 58 ff.); the KI.LAM festival (*KBo*, vol. 10, text 24, col. 5, ll. 1, 8); the *nuntariyasha* festival (*KUB*, vol. 10, text 48, col. 2, l. 7); and on the AGRIG list (*KUB*, vol. 26, text 2, reverse l. 4).

In the Iron Age, the kingdom is known only through attestations of its king, Warpalawa, who is referred to in inscriptions of Tiglath-Pileser III, to whom he paid tribute in about 740, 738, and 732 BCE (Hawkins and Postgate, 1988: 31–40 as Urballa the Tuhanean (i.e., *Tu'anean*). His father's name was Muwaharani (I) (IVRIZ 4 inscription) and clearly controlled the sites of Ivriz, Zeyve Höyük (alias Porsuk), and Bulgarmaden, as may be seen from the inscriptions of IVRIZ 1 and BULGARMADEN. Göllüdag may also have belonged to his kingdom. He was still on the throne as late as 710 to 709 BCE, when he is attested in a letter of Sargon II that identifies his kingdom as squeezed between that of Mita of Muški (Midas of Phrygia) and that of the Assyrian governor of Cilicia (see Parpola, 1987, no. 1). The Old Phrygian inscriptions found at Kemerhisar are connected with Mušķi/Midas and doubtless belong to this period. Warpalawa was succeeded by his son Muwaharani II, whose stela was found at Niğde (NIĞDE 2).

In the classical period, the fortified mound of Tyana (at Kemerhisar) was attributed by Strabo to Semiramis (*Geog.* 12.537). The occasional Hellenistic, Roman, and Byzantine historical references to Tyana are supplemented by inscriptions found in the province.

J. D. HAWKINS

TYRE, site located on one of two sandstone reefs about 2 km off the coast of southern Lebanon (32°16′ N, 35°13′ E). Classical tradition states that King Hiram (969–936 BCE) joined the two reefs with landfill, enlarging the city to about 40 acres. In succeeding reigns, further enlargement allowed the creation of ports on the northern and southern sides of the island. This island stronghold was joined to the mainland by Alexander the Great in 332 BCE, who constructed a causeway from the mainland in order to subjugate the city. By Roman times sand from sea currents quickly built up against this causeway, forming the present isthmus. Tyre was essentially an administrative and religious center dependent on food and water supplies from its "sister town," Ushu, on the coast, which stood amid rich and well-watered agricultural land. Ushu is known only from literary references as it lies beneath the modern city.

Excavations at Tyre, undertaken since the 1830s, have concentrated on the Roman and Byzantine remains on or just below the surface, with little attention given to pre-classical times. This omission was partially addressed by a limited excavation on the site of the original city by Patricia Bikai in 1973–1974, working under the auspices of the Lebanese Department of Antiquities. Her excavation extended to bedrock and produced a general building and pottery sequence for most of the period from about 2700 to 700 BCE. This excavation remains the basis for the archaeological history of Tyre before Hellenistic times (see below). A large gap in this sequence occurs in about 2000–1600 BCE, during which time the city may have been abandoned.

In 1990 the appearance of quantities of burial urns, funerary pottery, inscribed Phoenician stelae, and jewelry on the local antiquities market signaled a major discovery found by clandestine digging. The artifacts were traced to a site on the mainland close to the Roman hippodrome. While most of the material illegally discovered has been sold, scientific excavations are underway to recover what may be an important cemetery dating from the end of the Late Bronze Age into the Iron Age, about 1300 to 500 BCE.

Bronze Age. Literary references to Tyre are alleged in the Ebla texts (third millennium) and in the Egyptian Exe-

cration texts (c. 1800 BCE); however, the first is incorrect, the second uncertain. [*See* Ebla Texts.] The earliest reliable occurrences are in the Ugaritic texts and the Tell el-Amarna letters (Late Bronze Age). [*See* Ugarit Inscriptions; Amarna Tablets.] From that time onward, Tyre regularly appears in Egyptian, Assyro-Babylonian, Persian, and other contemporary texts, attesting to its importance as a major trade stronghold on the Mediterranean coast.

Herodotus, who visited Tyre in the mid-fourth century BCE, reports, on the authority of local priests, that the city had been founded some 2,300 years previously—that is, in about 2750 BCE (*Hist.* 2.44). Whether by coincidence or because of actual records maintained in the city archives, this date corresponds closely to the earliest known archaeological material. Little is known of the city in this early period, but in Bikai's limited sounding, which reached the lowest strata, remains of large stone walls and other occupational evidence were found (Bikai, 1978). Tyre was therefore already a permanent town in the Early Bronze Age II and there is clear evidence for houses and occupation in the following EB III. There is as yet no explanation for the apparent abandonment of the site during the entire Middle Bronze Age (c. 2000–1600 BCE). A sterile layer of sand a meter and more thick separating the Early and Late Bronze Age levels indicates that the site probably remained unoccupied during this time.

In the earlier Late Bronze Age, the site was used for burials and storage pits, but the city was not rebuilt until the late fifteenth century BCE. A century later, the correspondence of its ruler Abimilki to the Egyptian Akhenaten (included in the Amarna letters) shows that Tyre was then a client state of the Egyptian Empire. Abimilki was most concerned with the advance of Sidonian forces into his territory, their capture of the mainland town Ushu, and the resulting lack of water and food normally supplied to Tyre by that town. Once Egyptian rule was restored in Canaan, Tyre resumed its vassal status through the rest of the Late Bronze Age.

There is some disagreement in the literature over the fate of Tyre and other Phoenician cities during the critical twelfth century BCE, when the LB palace economies collapsed and the new socioeconomic structure of the Iron Age was being formed. This was the result, largely, of growing populations, overtaxation, and the like, but newcomers from the Aegean world, the so-called Sea Peoples, also played their part. They invaded Anatolia, destroyed major coastal cities such as Ugarit on the North Syrian coast, took over Cyprus, and may even have attempted an invasion of Egypt. On the other hand, the archaeological record at Tyre, Sarepta, and other Phoenician sites shows no destruction, and literary works of about 1100 BCE indicate that four of the primary coastal cities—Tyre, Sidon, Byblos, and Aradus—were then thriving trade centers. [*See* Sarepta; Phoenicia; Sidon; Byblos.] Trade between Cyprus and Tyre is well in evidence in the period; it is possible that the founding of the Tyrian colony at Kition (Larnaca) took place this early. [*See* Cyprus; Kition.]

Iron Age. During the early part of the Iron Age (c. 1150–900 BCE), the Phoenician cities were free to develop their own economies: the older empires were gone, and the empires that would arise in the east had not yet been formed. Tyre and the other Phoenician cities were thus untroubled by foreign intervention. The strong port cities that developed during this period embarked on a westward expansion into the Mediterranean, certainly led by Tyrian merchant fleets. While many reasons are suggested for this, the most important was the search for new sources of metal to support a growing Phoenician industrial complex in the manufacture of bowls, jewelry, and other metal objects. A welcome by-product of the search for metal was the creation of a trading empire that provided new customers for Phoenician products. Cyprus, with its rich sources of copper was the logical first step; evidence of a Phoenician commercial presence on Cyprus exists in the eleventh century BCE. By the eighth century BCE, Phoenician merchants had reached the silver, tin, and copper mines of Spain, a route maintained by Tyre that established small trading and way stations along the coast of North Africa. [*See* North Africa.] Among these was Carthage, later to become a large and independent urban center challenging Rome for domination in the western Mediterranean. [*See* Carthage.]

At this time, Tyre also engaged in commercial expansion to the east under King Hiram I (969–936 BCE), to whom Herodotus (*Hist.* 2.44) ascribes the enlargement of the city by the joining of the two original islands and the rebuilding of harbors and temples. Tyrian expertise in architecture and crafts was thus already well-known when Hiram contracted with the new Hebrew monarchy in the Canaanite hill country to help construct King David's palace and Solomon's Temple in Jerusalem. [*See* Jerusalem.] In addition, Hiram and Solomon entered into a joint maritime venture between the Red Sea port of Eilat (Ezion-Geber) and Ophir (probably on the Somali coast). It is difficult to assess the extent of Tyre's political influence then and in the succeeding centuries. It certainly appears to have been the leading Phoenician commercial center and had treaty relationships with neighboring states—the best known being that of the marriage of the Tyrian princess Jezebel to King Ahab of Israel (*1 Kgs.* 16:31–32). However, there is no real proof of Tyrian hegemony over other Levantine cities or Tyrian rule over eastern Cyprus, as is sometimes suggested. The question has been obscured by the metonymic use of *Sidonian* to refer to Phoenicians in general. A Phoenician text from Cyprus, for example, refers to a Tyrian ruler as "king of the Sidonians" and the Hebrew Bible (*1 Kgs.* 5:6) calls the inhabitants of Tyre "Sidonians."

During the period of Assyrian domination (883–612 BCE), Tyre, like the other Phoenician coastal cities, was not subjected to outright conquest and occupation. [*See* Assyrians.] The Assyrians, rather, imposed tribute and taxes; as long as those were forthcoming, there was no need for military action. The Levantine cities presented no real threat to Assyrian security, and it was in land-locked Assyria's interest to maintain firm but limited control over the Phoenicians' rich Mediterranean commercial empire that produced their annual tribute. A ninth-century BCE engraved bronze band from an Assyrian palace gate now in the British Museum portrays the island fortress of Tyre and Assyrian ships rowing Tyrian tribute to the mainland. Revolt against this mild Assyrian rule was swift and merciless. The first recorded siege and destruction of a Phoenician city is that by Sennacherib (704–681 BCE), who punished Sidon and other towns, including Ushu and the northern Canaanite cities of Achziv and Akko, for their refusal to pay the annual tribute. [*See* Achziv; Akko.]

Sidon was again destroyed under Esarhaddon (680–669 BCE), who also put down the revolt of a coalition led by King Baal of Tyre. A treaty between Esarhaddon and Baal restored Tyre's dependencies stretching south into Philistine territory but gave an Assyrian official resident in the city far-reaching authority over its commerce. The final Assyrian assault in Phoenicia was by Ashurbanipal (668–627 BCE), again against Baal of Tyre, who once more had refused to acquiesce to foreign domination. Tyre was forced to submit through the simple expedient of cutting off its mainland food supply.

Toward the end of the seventh century BCE, Assyria was conquered by Babylon; during the reign of Nebuchadrezzar (604–562 BCE), the former Assyrian vassals in the west were absorbed into the new, but short-lived, Babylonian Empire. Josephus (*Against Apion* 1.56) records a long siege of Tyre; although the city was not taken, Tyre became a vassal under resident Babylonian officials, one of whom is named in a series of letters from Tyre to the Babylonian court. Shortly thereafter, the Persians, under Cyrus II, incorporated all the western provinces into their own empire.

Persian Period. Throughout the long period of Assyrian and Babylonian domination in Phoenicia, Egypt played a passive role in Levantine affairs. There is solid evidence of trade connections, especially in southern Canaan and with the coastal cities, including Tyre. Egypt sent contingents of troops to join northern coalitions against Assyria, but these were always defeated. At about the time of the fall of Nineveh in 612 BCE, Pharaoh Psammetichus I, founder of the twenty-sixth dynasty, claimed suzerainty over the Phoenician cities; his successor, Necho II, is generally credited with a short period of rule in southern Canaan, although there is little evidence to support this. Herodotus notes that Pharaoh Apries (589–570 BCE) sent an army against Sidon and fought a naval battle with Tyre, a reference that may reflect Egyptian aid to Tyre during Nebuchadrezzar's siege of that city. In general, Egyptian political influence in Canaan was intermittent and without any real lasting effect.

With the fall of Babylon in 539 BCE, Phoenicia came under Persian dominance and, along with Cyprus and Egypt, constituted the fifth satrapy of the Persian Empire, with Sidon as the seat of the Persian governor and his administration. The Persians had a vested interest in both the western commercial ties of the coastal cities and their fleets, which became part of the Persian military forces in their unsuccessful attempt to conquer Greece. Persian dominance gave Phoenicia a period of relative peace and prosperity, situated as it was in the center of a trade network stretching from Gibraltar to Persia, from the Caucasus to Nubia. The introduction of coinage, first at Sidon, in about 450 BCE, greatly facilitated this international commerce; Tyre, Aradus, and Byblos began minting coins soon thereafter.

The prosperous and peaceful life of the Phoenician cities was interrupted by revolts from time to time, especially in the fourth century BCE, encouraged by both Greeks and Egyptians. Several cities saw this as an opportunity to rid themselves of Persian influence in local affairs, although the population was divided between its Greek and Persian sympathies. In 392 BCE, Tyre either joined with or submitted to Evagorus I of Salamis, who was aided by Athens and Egypt, during his war to unite Cyprus and free the island. [*See* Salamis.] This failed and, although Evagorus retained his throne, Tyre reverted to Persian authority. Other rebellions by Sidon in 362 and 347 BCE were also put down, in the latter case with the destruction of the city. The role of Tyre in these revolts is obscure. Persia was thus able to maintain control over Phoenicia, but rising pro-Greek sentiments, Egyptian interference, and the desire to escape Persian rule helped pave the way for the Macedonian conquest.

Hellenistic–Roman Periods. In 332 BCE, after a seven-month siege by Alexander the Great, who constructed a mole to the island (see above), Tyre capitulated to yet another empire. Under Alexander's successors, the Seleucids, Tyre prospered; by Roman times it had become a major commercial center in the east. It is essentially the Roman city that is visible today, along with later Byzantine remains. A paved road with extensive necropoleis on either side led from the mainland through a monumental archway into the city proper. [*See* Necropolis.] Inside the archway, the city's central colonnaded street with shops along either side has been largely reconstructed by the Lebanese Department of Antiquities. An aqueduct ran beside this street bringing water from a mainland spring. [*See* Aqueducts.] The major features of the Roman city are a huge Roman bath and a hippodrome, one of the largest in the Roman world, that could seat some sixty thousand spectators. Later structures include a fourth-century basilica and a Crusader cathedral.

U

UBAID (Ar., Tell al-'Ubaid), site located 6 km west of Ur, on the right bank of the Euphrates River in Iraq (30°58′ N, 46°05′ E) that has given its name to the last period of the prehistory of Mesopotamia. This small mound, 350 m long and 6–7 m high, was explored on behalf of the British Museum in 1919 by Harry R. Hall (1922), who recovered painted sherds, now known to be similar to those from Eridu that, at the time, he could compare only with those collected at Susa, in the Iranian province of Khuzistan. He also discovered several later objects—fragments of columns inlaid with stone mosaic and copper animals. In 1923–1924, C. Leonard Woolley, responsible for the exploration of the large neighboring site of Ur, carried out a productive excavation at Ubaid, resuming Hall's work. Woolley explored the historical as well as the prehistoric strata. He initiated the use of the name *Ubaid* for the long period with painted ceramics whose traces he also explored in soundings at Ur. This terminology, accepted by all, is still in use. Finally, in 1937, Pinhas Delougaz (1938) and Seton Lloyd (1960), who were working at the time on behalf of the Oriental Institute of the University of Chicago at Khafajeh, in the valley of the Diyala River in central Iraq, worked at Tell al-'Ubaid. In only four days at the site they discovered that the great temple excavated by Hall and Woolley was the same type as that at Khafajeh, but with an oval circuit wall. The site has not been excavated since. [*See* Khafajeh.]

The periodization of the prehistoric occupation of Ubaid was definitively set in 1960 by Joan Oates, based on analysis of the ceramics from Eridu, which was occupied during nearly the entire Ubaid period. [*See* Eridu.] Two new phases have been added to her subdivisions (Ubaid 1–4, early–late): Ubaid 0, the earliest (recognized at Tell el-'Oueili and several sites surveyed but not excavated), and Ubaid 5, the latest (attested at 'Oueili, Ur, Tell Madhhur, and several sites in the Arabian Gulf). [*See* 'Oueili, Tell el-; Ur.] In terms of absolute chronology, according to the most recent carbon-14 datings obtained at 'Oueili, the Ubaid began in about 6200 BCE, Ubaid 4 lasted from about 4800 to 4300 BCE, and Ubaid 5 from about 4300 to 3800 BCE.

At Tell al-'Ubaid, the habitation area, investigated in a trench 30 × 2.1 m opened in the center of the mound, seems to have consisted of houses of light construction—wattle or straw matting layered with pisé—essentially reed hut, plastered with mud that did not preclude the use of pivot stones. The material recovered did not permit distinguishing between an Ubaid 4 or 5 dating, but it certainly indicated a very late Ubaid date: the finds consisted of painted and especially monochrome pottery, sometimes incised; sickles and pestles of baked clay; grooved balls of clay; fragments of sickles with large flint teeth; limestone hoes; small polished axes; and terra-cotta figurines. The lightly constructed huts at Tell al-'Ubaid, which must date to 4000–3800 BCE, demonstrate the fact, also observed at Ur, that in lower Mesopotamia, at the end of the Ubaid period, housing was made of light materials. The only important constructions were probably the large family or clan reception rooms (as at Eridu VII–VI) or the granaries (as at 'Oueili). [*See* Granaries and Silos.]

A short distance south of the trench, a vast cemetery was surveyed. The site's British excavators covered the area rapidly because of the apparent poverty of the remains. They uncovered ninety-four tombs that represent a vast period of time (Ubaid 3–4, 5000–4300 BCE)—only three of which seemed on the basis of the pottery found there to belong to the final phase of Ubaid. To the north of the cemetery and sounding, excavation uncovered a single structure, a large temple whose foundation date is not known. In fact, the only stage of the building excavated was a reconstruction, according to the text of a stone foundation tablet, by "A-anepada, king of Ur, son of Mesannipadda, king of Ur, for Ninḫursag." The king Mesannipadda, of the first dynasty of Ur, reigned in about 2500 BCE. This great sanctuary strongly resembles the Oval Temple at Khafajeh and one found at Lagash, present-day al-Hiba, not far from Telloh. [*See* Girsu and Lagash.] These vast structures set in an oval enclosure wall and identified by inscription, are clearly separate from the surrounding habitation areas, which is especially evident at Khafajeh. They are very isolated, not only by their enclosure wall, which fits poorly into the urban design, perhaps on purpose, but also by the terrace on which they are set. At Tell al-'Ubaid, the great oval enclosure wall (85 × 65 m) was probably doubled in the interior by a concentric, smaller enclosure (as at Khafajeh). A rectangular terrace 33 × 26 m was constructed in the center of the en-

closure of unbaked plano-convex bricks on a stone socle. Perpendicular to its southeast facade, a staircase with several stone treads gave access to the summit of the terrace. In addition, a small lateral stair, also of stone, was arranged parallel to the southwest facade, which was later incorporated in an annex. The sanctuary itself, which has since disappeared entirely, probably stood on this terrace.

At the foot of the terrace, on either side of the principle stair, Hall and Woolley retrieved numerous decorative elements fallen from the facade, or perhaps from the doors. Some scholars think that the decoration was located next to the main staircase leading to the terrace. All the objects are presently housed in the British Museum. The finds include eight copper bulls with a wood and bitumen core, the small heads of birds and of a lion; the heads of leopards; a large copper plaque (2.38 × 1.07 m) representing an eagle, perhaps lion-headed, grasping two stags; numerous clay nails whose heads are in the form of a flower; stone birds; and copper columns ornamented with stone mosaics. Also found were the elements of a decorative panel out of shells, set into bitumen, that represents a rare milking scene (see Gouin, 1993); and some fragments of statuary in the round. These sparse and scattered vestiges demonstrate the extraordinary wealth of ornamentation in this sanctuary, which continued to be maintained, in particular by Shulgi, king of the third dynasty of Ur, in about 2100 BCE. They are the most beautiful examples known of the decoration of a great Sumerian sanctuary in the middle of the third millennium BCE.

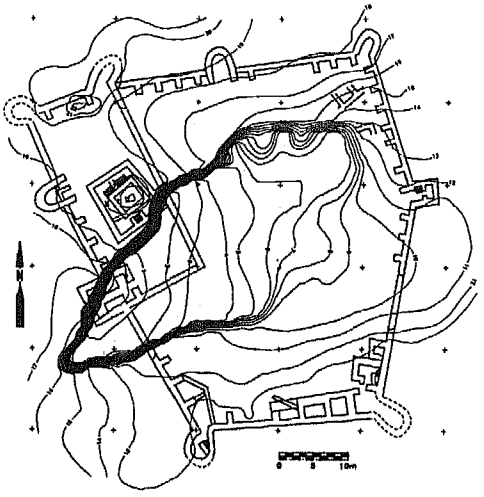
Translated from French by Nancy Leinwand

UBAR (alternately Wabar/Aubar), a region/city in the proximity of the Rub al-Khali sand desert of southern Arabia or a location to the south of it somewhere near eastern Yemen or western Oman (18°15′31″ N, 53°39′05″ E). Medieval Arabic sources point to Ubar as a land in eastern Yemen. Early Islamic Arab historians suggest that the region was connected to the land of the Mahra, near al-Shihr, and al-Akhaf (Tkach 1897, pp. 1832–1837; 1913a, pp. 1073–1074). Originally, the region reportedly was well irrigated, forested, and had many fortresses and palaces. In the local tradition, destruction was brought down on the people by their wickedness, and the ruins became choked with sand from great winds or drought. Eventually, the area was abandoned. Several authors tie the Ubar area to both the Mahra and the long-lost people of Ad. The assumption that Ubar was a single city comes from the more fanciful embroideries of the *Thousand and One Arabian Nights,* particularly the stories "The Keys of Destiny" and the "City of Brass."

Other than St. John Philby in the early 1930s (1933, pp. 157–180), few Westerners have searched for Ubar/Wabar. A key to the mystery is in the term *Iobaritae* used by Ptolemy (6.7.24) to define a tribal group living inland of the region known as Sachalitai (Stevenson, 1932, pp. 137–140). Both terms appear in modern Dhofar on copies of Ptolemy's map and in the *Periplus of the Erythraean Sea,* among other terminology consistent with a locality in the northern Indian Ocean (Casson, 1989, pp. 170–173). Central to the matter is identifying the Iobaritae with the Islamic term *Ubar.* J. Tkach thought the people of Ubar lived in deep antiquity and had disappeared prior to the coming of Islam (1913a, p. 1074). In the nineteenth century, Western scholars argued that the Iobaritae were the later Ubars (Tkach, 1897, p. 1836). Scholars are divided today on the connection.

With the first investigations at Dhofar in the late 1950s, the site of Khor Rori (long identified with Moscha of the *Periplus* account), was confirmed to be ancient SMHRM (Albright, 1982, cf. the arguments on pp. 3–10; Doe, 1983, pp. 147–150). Its gateway inscription in Epigraphic South



Arabic specifically mentions the S'KLHN frankincense district (Albert Jamme in Albright 1982, pp. 42–45; Pirenne, 1975; Beeston, 1976) and supports the term *Sachalitai* used by both the *Periplus* and Ptolemy. Based on the archaeological survey on the Salalah plain (1992–1995), it is debatable, however, if the term *Moscha Limen* used by the *Periplus* is to be identified with the Khor Rori location (see Doe, 1983, p. 21) because SMHRM = Moscha is largely conjectural. Ptolemy's harbors and settlements on the Salalah plain can now be more readily identified, based on the current archaeological survey of this region carried out by Juris Zarins. At least seven major sites from Khor Rori to Raysut (and perhaps Mughsayl) must be considered in reference to Ptolemy's locations.

It appears that Ptolemy's placement of the Iobaritai in the hinterlands behind the Sakalan region is also accurate (*contra* Groom 1994, pp. 207–208). The three localities (Iula, Marimatha, Thabane) identified with the Iobaritae may be tied into the Mahra occupation of the region. These identifications are contingent on solving problems of scale and on the distortion inherent in all copies of Ptolemy. (For the contemporary distribution of the Mahra, see Dostal, 1967, and Lonnet, 1985; as a contemporary term in the classical period, see Müller, 1991.)

Bertram Thomas's observation that the road to Ubar (1932, p. 161; see also Groom, 1994, p. 208) headed into the Rub al-Khali was the basis for the recent investigations by Zarins and the Jet Propulsion Laboratory Scientists Ron Blom and Robert Crippen into the location of Ubar. LANDSAT/SPOT/THEMATIC MAPPER remote-sensing images supplied by the Jet Propulsion Laboratory of the area Thomas noted recorded a long route beginning near Wadi Mitan through the southern Rub al-Khali. Projecting the route northward, the destination would have been either Ayun/Layla in the central Tuwaiq Mountains or the oasis of Jabrin on the northern edge of the Rub al-Khali (Philby, 1933, pp. 86–106). Archaeological work in the Rub al-Khali discredited the theory that large, permanent settlements belonging to the Ubar region would have been located in the sands (Edens, 1988). Tracing the tracks Thomas discovered back to the nearest ancient permanent source of water led to the discovery of Shisur (Ar., "cleft," or "fissure"). Known to explorers since Thomas (1932, p. 136) and Wilfred Thesiger (1984, p. 100), and even visited by archeologists in 1973 (Pullar, 1974, p. 41; 1975, pp. 49, 71–73) the site and region were not systematically investigated until 1990–1992.

A brief surface examination of the Shisur promontory led to a detailed study of the site and region by Zarins in 1991–1992 as director of the Transarabian Expedition. Data from this study and the excavations (1992–1994) now confirm that the site is most likely Marimatha, the largest settlement on Ptolemy's map, in the territory of the Iobaritae. The Shisur site, apparently a collapsed limestone cavern, is now a large sinkhole. Earthquake activity ruptured the aquifer beds (Umm ar-Radhuma A–B) and water flows to the surface in several springs. Fracturing and sink-hole collapse have been seen at Shisur and in the surrounding area. The events shaping the region's current geomorphology are dated to the last phases of the Pleistocene. Wadi Ghadun, 2 km (1 mi.) west of Shisur, represents the region's other major geomorphological feature. The now dry stream was a major feature during the Pleistocene and Early Holocene, flowing past Shisur and skirting the Rub al-Khali, 25 km (16 mi.) to the north.

A preliminary assessment of the site's history is based on the excavation of 3-meter squares laid in a large grid. The earliest human activity belongs to the Neolithic period (phase III, c. 3500–2500 BCE), although more than twenty-five sites of the period are known around Shisur that extend occupation back to about 6000 BCE (phase I). Possible Upper Paleolithic (100,000–40,000 BP) materials may be located to the east. Nondescript stone tools at Shisur may belong to the Bronze Age (2500–1000 BCE), but any formal buildings date to the Iron Age (c. 1000–0 CE). Ceramics only appeared in the region, at Dhofar (Tkach, 1913b), in the Iron Age—in contrast to Yemen (2500 BCE) and northern Oman (4500 BCE), so that investigations are focusing on the structural and material culture sequences of the Iron Age and later. [*See* Yemen; Oman.]

The earliest fortress at Shisur may be Early Iron Age. A small enclosure protecting the springs was built with semi-dressed stone walls with interior partitions. Both detailed stratification and the material culture suggest that the fortress was enlarged in the Iron Age and that occupation peaked in the early first centuries CE. The walls of the fortress were then enlarged, more interior rooms were added, and a proper gate and additional towers were built. The material culture resembles that of both Yemen (imported raw chlorite schist, sandstone, and basalt, which were crafted into finished products) and northern Oman (Parthian red wares connected to Sohar). [*See* Sohar.] The distinctive red-burnished wares with dot-and-circle/rouletting motifs have yet to be identified outside Dhofar. Other Hellenistic wares with appliqué point to connections with eastern Saudi Arabia, specifically the Jabrin, Thaj, and Dammam regions. [*See* Thaj.] After a four-century hiatus (c. 400–800 CE), probably caused by earthquake activity that destroyed a large portion of the site, or economic collapse the complex was formally reoccupied in the ʿAbbasid period and finally abandoned by 1400. Excavation at the bottom of the sinkhole revealed more than 5 m of occupation, all attributable to bedouin use since 1400.

The region surrounding Shisur parallels the focus of the central formal complex. Especially to the east, campsites and small-scale satellite occupation can be seen for more than 10 km (6 mi.) along an arc of small hills. At Hailat Araka, 40 km (25 mi.) away, a similar occupation pattern may be

present: limited examination yielded principally large-scale Neolithic and possible Bronze Age occupations. Irrigation channels and fields reported at Shisur are now obscured by modern oasis and farm activity (Thomas, 1932, p. 131). This situation may parallel the ʿAin Humran complex on the Salalah plain, where irrigation channels and field walls can still be seen.

As a whole, the Shisur region, because of its perennial water supply, was the focal point of commerce and agriculture. Based on Ptolemy's observations, it appears that the Iobaritae were the ancestors of the Mahra peoples inhabiting this plain and conducting incense trade across the Rub al-Khali and elsewhere. The smaller satellite sites with perennial water dot the backslope of the Nejd. Ptolemy's sites of Iula and Thabane may be Andhur and Mudai (or Habarut), respectively, in Dhofar. Following the collapse of the incense trade and possible topographical changes in the region caused by climate and/or earthquake, the Mahra retreated to the mountains to the south sometime after the tenth century (Dostal, 1967, pp. 123–135, esp. fig. 19). The medieval Arab trade network through the region was destroyed by the Portugese in the fifteenth century (Guest, 1935, pp. 407–408).

JURIS ZARINS

ʿUBEIDIYA, hilltop site about 0.5 km east of Tell ʿUbeidiya and west of the Jordan River, on a mound whose slopes range from 160 to 205 m below sea level. Geologically, this formation was originally named *Melanopsis stuffe* (Picard, 1943) and later as the ʿUbeidiya Formation (Picard and Baida, 1966). Excavation of the prehistoric site of ʿUbeidiya was sponsored by the Israel Academy of Sciences, under the direction of Moshe Stekelis (1960–1966) Ofer Bar-Yosef and Eitan Tchernov (1967–1974), and more recently with Claude Guérin of the University of Lyon (1988–1994).

The site's numerous angled and folded layers, excavated with heavy machinery, contained animal bones and worked stone artifacts. The formation reflects the depositional history of a Lower Pleistocene freshwater lake and its immediate environment. The lake occupied the area now covered by the Sea of Galilee and an additional 30 km (18 mi.) to its south. More winter rain was experienced then, so that oak forests at times covered the valley slopes of the central Jordan Valley. Stratigraphically, the excavations exposed a sequence of expansion and retreat for the ʿUbeidiya lake. Its final regression, caused by tectonic movement, may also have been responsible for its disappearance (Picard and Baida, 1966). [*See* Jordan Valley.]

A series of trenches revealed more than sixty layers on both sides of a small anticline. Many of the archaeological horizons exposed may have been continuous on the other

side of the anticline before the top was completely eroded. Numerous artifacts were recovered from the different layers, including core-choppers, polyhedrons, spheroids and subspheroids, handaxes, picks, and abundant retouched and unretouched flakes. Those artifacts that had originated in the gravelly beach contexts tended to be abraded, whereas the least frequently abraded items were recovered from clayey layers.

The site's main tool groups can be grouped according to the raw materials used: core choppers, polyhedrons, and many flakes were made of flint; spheroids from limestone; and handaxes from basalt, with a few from limestone and flint. The size of the desired shape probably dictated the choice of the raw material. The site's lithic assemblages resemble those of the lithic industries of the Developed Oldowan and Early Acheulean in East Africa's Olduvai Gorge, specifically Upper Bed II (Bar-Yosef and Goren-Inbar, 1993).

Faunal correlations and the paleomagnetic reversed position of most of its sequence provide a date for 'Ubeidiya of 1.0–1.4 million years ago. The extensive faunal collection is primarily Eurasian in origin, with only a few species from Africa. It includes more than one hundred species of mammals, reptiles, and birds, among them hippopotamus, horse, deer hedgehog, leopard, wild camel, lemming, bear, fox, rhinoceros, elephant, gazelle, oryx, and hamster. Those fauna originating in Africa include giraffe, a few species of rats, hippopotamus, warthog, and a species of wild sheep.

These varied fauna would have encouraged scavenging, and the Mediterranean flora made available leaves, fruit, and seeds to supplement the diet of early hominids. Although no human remains were found in situ, the worked-stone artifacts are presumably the work of *Homo erectus*. The rich archaeological and zoological information from 'Ubeidiya for the early Lower Paleolithic constitutes the best evidence for the movement of *Homo erectus* out of Africa.

OFER BAR-YOSEF

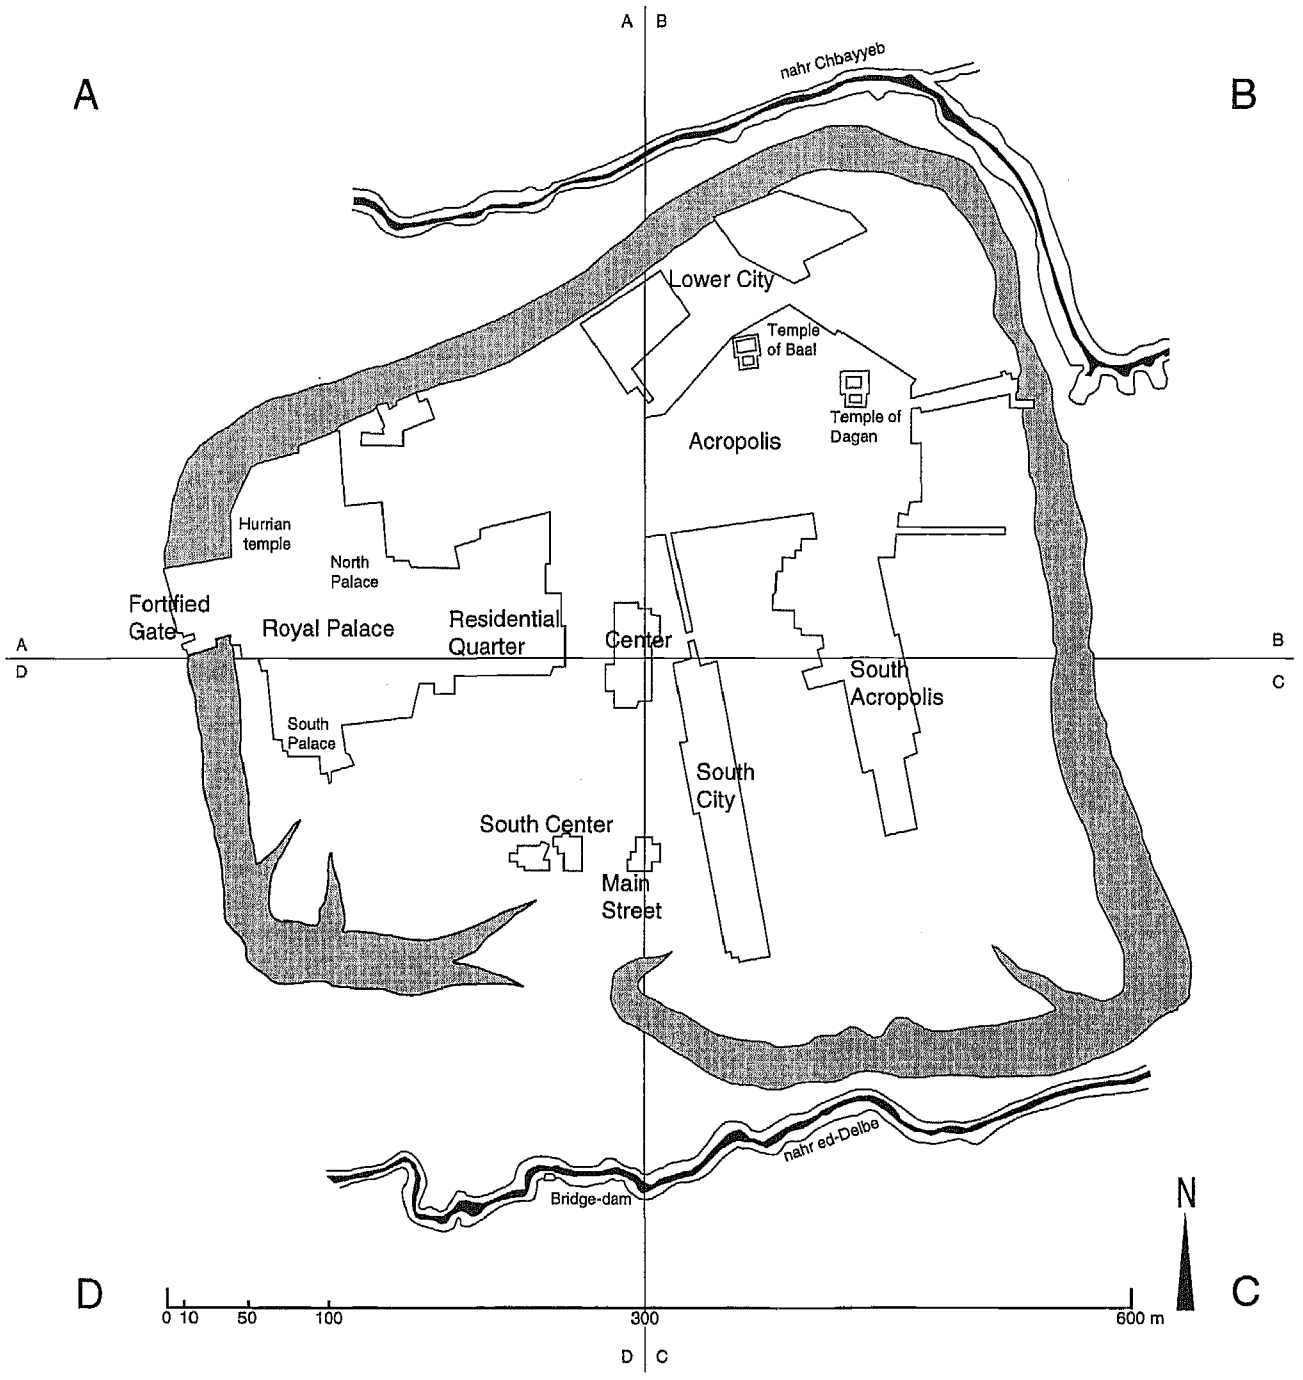
UGARIT, an ancient kingdom on the Mediterranean coast of Syria, whose capital of the same name was established on the mound of Ras Shamra, located 10 km (6 mi.) north of Latakia (35°36′ N, 35°47′ E). The mound of Ras Shamra is encircled by two small seasonal streams (Nahr Chbayyeb to the north and Nahr ed-Delbeh to the south) that join (Nahr el-Fidd) to flow into the bay of Minet el-Beida, about 800 m away; its broad agricultural plain divides the plateau of Bahluliyah, and the Alaouite Mountains from the sea. Five km (3 mi.) to the south lies the promontory of Ras Ibn Hani, where an Ugaritic settlement of the Late Bronze Age is located.

The kingdom extended for about 2,000 sq km (1,240 sq. mi.). It was bounded by the Mediterranean Sea (to the west); the Bayer and Bassit Mountains (to the north); the Alaouite Mountains (the so-called coastal chain of the Jebel Ansariyah), which are 1,567 m high (to the east); and the area of the Jableh and Nahr as-Sinn (to the south). A permanent river, the Nahr al-Kabir, drains the waters of the mountains to the north; its valley (to the northeast) opens the route to central Syria. On the northern horizon, the Jebel al-Aqra (1,780 m high) is ancient Mt. Sapanu (Mt. Zaphon; the Romans' Mt. Casius), where Baal, the storm god, resided.

The city visible on the surface of the mound is that of the Late Bronze Age (see figure 1). In its present state, it is defined by the surface area of the mound (more than 20 ha, or 49 acres), which does not correspond to the area of the LB town: to the northeast, more than 50 m were undermined by the meandering of the Nahr Chbayyeb; to the east, and especially the south, modern farming prevents examination of the extent of the ancient habitation.

In 1929, texts were recovered from the mound of Ras Shamra that were written in several languages. Among them was an otherwise unknown language, that of Ugaritic, inscribed in cuneiform writing according to a new alphabetic system. The texts revealed a new world of cultural, religious, and mythological traditions, essentially of the fourteenth–thirteenth centuries BCE, that further demonstrated the first-rank importance of Ugarit in the history of the Near East.

The interpretation of the texts discovered since 1929 at Ras Shamra led to the identification of the site as ancient Ugarit, mentioned in second-millennium BCE texts from Mari, Boğazköy, and Tell Amarna. Texts from Ebla have perhaps furnished the earliest mention of the name (2400



UGARIT. Figure 1. *Plan of the city.* (Courtesy M. Yon)

BCE) but it is questionable. [*See* Mari Texts; Boğazköy; Amarna Tablets; Ebla Texts.]

The port of Minet el-Beida is probably ancient Ma'ḫadu (Leukos Limen of the Greeks, the White Port of the Crusaders). There is some doubt about the ancient designation of the site of Ras Ibn Hani (Appu? Biruti? Rešu?). The single large river, the Nahr al-Kabir, is designated as Rahbanu. The Ugarit texts in Akkadian and Ugaritic from the fourteenth to the beginning of the twelfth centuries BCE enabled progress in localizing the ancient toponyms of the realm, sometimes identified by comparing them with present-day names. [*See* Ugarit Inscriptions.]

Archaeological Investigation. After the accidental discovery in 1928 of a funerary vault at Minet el-Beida, the Mission Archéologique Française, directed by Claude F.-A. Schaeffer explored the harbor foundation and then the mound of Ras Shamra 800 m from the shore (1929–1970). The mission was subsequently directed by Henri de Con-

tenson (1971–1974), Jean Margueron (1975–1977), and Marguerite Yon (since 1978). [*See the biography of Schaeffer.*]

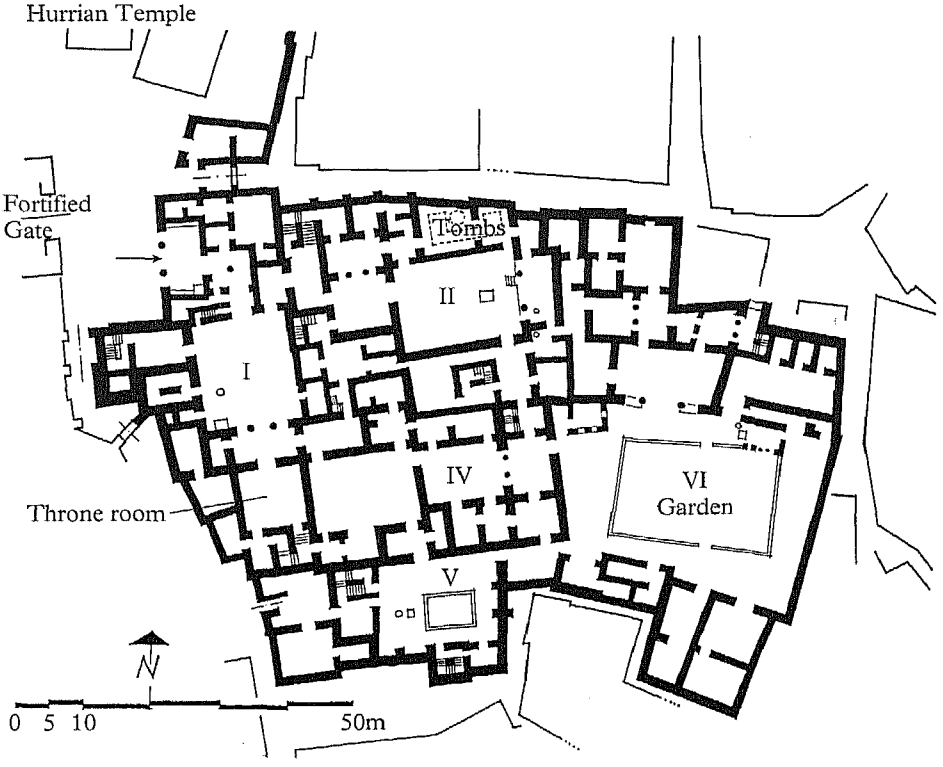
The first campaigns concentrated on Minet el-Beida's harbor settlement and tombs (1929–1935) and on excavating the mound of Ras Shamra. Urban areas were excavated on the Acropolis (1929–1937), including two temples and the House of the High Priest, with its mythological tablets and inscribed bronze tools that permitted the decipherment of Ugaritic in 1930 by Hans Bauer, Edouard Dhorme, and Charles Virolleaud. [*See the biography of Virolleaud.*] From 1932 to 1937, residential areas in the Lower City, East and West, and below the Acropolis (north and northeast) were explored.

Exploration of the northeastern part of the mound began in 1937–1939. Buildings were uncovered that are known as the Palace of the Queen Mother, the Building with Four Pillars, and the so-called Hurrian Temple. Excavation of the Royal Palace, with its fortification on the west, was begun at that time (see figure 2). It was resumed, after the discovery of the main archives, following World War II (1948–1955). The excavation of the once-inhabited areas to the east of the palace, the houses in the Residential Quarter, with their deposits of archives and rich furnishings, was continued between 1953 and 1974. Included in the monumental complexes sometimes recognized as palaces are the vast North Palace (excavated in 1968–1971), perhaps a royal palace that preceded the last royal palace; and the South Palace (the "Little Palace," or "House of Yabninu," excavated in 1964–1965), with its archives. Between 1959 and 1964, large north–south trenches revealed other habitation areas in the South City (1959–1960) and on the South Acropolis (1961–1964) that included important tablets. A post-Ugaritic installation in the middle of the mound (Persian and Hellenistic period) was excavated in 1971–1973.

Deep soundings were undertaken to explore periods earlier than the Late Bronze Age to the west of the Temple of Baal (1953–1960) and in the Garden of the Royal Palace, or court III (1954–1955). The most important of them, sounding H (1962–1974), on the west slope of the Acropolis, revealed 15 m of occupation and gave the most complete stratigraphy of the site (seventh–second millennia).

In 1975–1976, a large LB dwelling was excavated northwest of the mound. Since 1978, the project has focused on urbanism and architecture, including excavation of the area at the center of the city and an architectural study of the South City Trench (excavated in 1959–1960). A square opened in the southern area (South Center) produced new batches of tablets in an archaeological context, the "house of Urtenu" (1986–1994). A study of the urban topography led to the opening (since 1992) of a square on the Main Street, the principal access route in the city, on the axis of the bridge-dam (excavated 1988) that crossed the Nahr ed-Delbeh to the south.

The emergency excavation of a small mound next to the sea at Ras Ibn Hani (about 5 km, or 3 mi., from Ras Shamra) uncovered a new Ugaritic settlement with a palace, fortifi-



UGARIT. Figure 2. *Plan of the Royal Palace.* (Courtesy M. Yon)

cations, and texts (thirteenth–twelfth centuries BCE) and a Hellenistic fortress. The site was explored by a Syro-French expedition directed by Adnan Bounni and Jacques Lagarce. [*See* Ras Ibn Hani.]

Stratigraphy and Chronology. The best-known period on the mound of Ras Shamra in terms of texts and archaeological remains is the Late Bronze Age, in particular the fifteenth–twelfth centuries BCE). It is the apex of a history five millennia long.

Neolithic period. Human occupation by farmers, hunters, and fishermen began in the period of sedentarism in Syria-Palestine (level VC, seventh millennium). Subsequently (levels VB, 6000–5750 BCE; VA, 5750–5250 BCE), new technologies appeared: the breeding of domesticated animals, houses built of stone according to a rectilinear plan, and the manufacture of containers (the "white ware" of plaster and baked ceramic).

Chalcolithic period. In the Chalcolithic period (level IV), new influence from the East led to a profound transformation and reduction in the size of the inhabited area. The site's Halaf phase (5250–4300 BCE) is characterized by painted pottery, diversified architecture, the development of crafts, and the breeding of small livestock. Its Ubaid phase (level III C–B, end of the fifth–fourth millennia) witnessed the appearance of copper. [*See* Ḥalaf, Tell; Ubaid.]

Early Bronze Age. After about 3000 BCE (level III A), occupation of the site evolved considerably. The Early Bronze stratum presented urban characteristics (alleys, a city wall). The site's architecture, formerly of unbaked brick (phase 1), utilized stone more and more. Tools, mainly of stone, now also included metal objects (copper, bronze). Pottery demonstrated relationships with the contemporary sites of Cilicia, North Syria, and Palestine. Phase 3 showed a rapid development of bronze metallurgy (weapons, tools). In about 2200 BCE, the mound was abandoned, like other sites in the Levant, for a period of about a century (or two?).

Middle Bronze Age. In about 2000 BCE (level II), the site began a new life, with the arrival of nomadic populations that settled in Syria (cf. Amorites). Certain groups *(porteurs de torques)* seemed expert in metallurgy (molds for jewelry and weapons were recovered). The architecture of phase 1 is not known, only its large collective tombs. In phases 2 and 3 (c. 1900–1650 BCE), a new urban civilization united the Syrian coastal traditions and the new influences. The town, which gradually covered the entire surface of the mound, was protected by a strong wall. [*See* Amorites.]

Two temples on the Acropolis and the Hurrian Temple northeast of the mound may have their origin in the Middle Bronze Age. Excavation has produced many objects from the Middle Bronze period, notably Egyptian, with hieroglyphic inscriptions. Some scholars have proposed the political domination by pharaohs of the twelfth dynasty. The name *Ugarit* is also mentioned in the Mari texts (royal visits, the trade in tin), which attests to continued relations between northern Mesopotamia and the coastal realm (Courtois, 1979; Saadé, 1979).

Late Bronze Age. The end of the MB period (c. 1650 BCE) and the phase that followed (until the Amarna period, fifteenth century BCE) remains an obscure period in the Levant. The building called the North Palace was probably constructed at the beginning of the Late Bronze Age. The Late Bronze level I at Ugarit experienced a new expansion of urban development, spectacular prosperity, and the growing importance of royal power (fifteenth–thirteenth centuries BCE). The succession of kings and their relations with foreign powers are known from the texts found in the archives of Ugarit and elsewhere (e.g., Amarna) and by the seals that mark official documents. [*See* Seals.] The written documents give evidence for the use of several languages, mainly Akkadian and Ugaritic.

The history of the kingdom of Ugarit is tied to the powers that surrounded it and on which it depended (Mitanni, Egyptian, Ḫatti) and to neighboring realms—friendly or hostile, according to the circumstance or period (Carchemish, Amurru, Siyannu, Qadesh, Tyre, Sidon, Byblos, Berytus/Beirut). In about 1400–1350 BCE, Ugarit fell under Egyptian control. After 1350 BCE, the expedition of the king of Ḫatti, Šuppiluliuma made the Mitanni submit to Hittite domination. Ugarit, Amurru, Qadesh, and other small kingdoms also passed into the Hittite sphere of influence. [*See* Mitanni; Carchemish; Tyre; Sidon; Byblos; Beirut; Hittites.]

In the latter half of the thirteenth century BCE, the royal authority monopolized the wealth of Ugarit. The kingdom was founded on a flourishing economy, but its weak military capacity continued to fail. Ugarit was probably destroyed at the beginning of the twelfth century BCE, in raids by the Sea Peoples, who plundered and set fire to it and numerous other sites. [*See* Philistines, *article on* Early Philistines.] The annihilation of Ugaritic civilization necessarily had other causes as well—economic, social, and political—that explain the total and final abandonment of the town by its inhabitants in about 1180 BCE. Evidence of occupation in the later Persian and Hellenistic periods only appeared in a small portion of the site south of the Acropolis (Stucky, 1983).

Fortifications. The MB city was surrounded by ramparts (see figure 3) for most of that period. To the north, erosion caused their disappearance, except to the north of the Acropolis, where portions were found in a sounding (1934). Soundings revealed the remains of a wall to the east, as well. To the south, here and there below earthen embankments, traces of a Main Street appeared that ran from the south toward the center of the city.

To the east, an imposing fortification protected the access to the Royal Palace: a stone glacis (a 45-degree slope), a square tower (14 m on a side) protecting a pincer gate and hidden access by a ramp (now disappeared), and a postern leading behind the tower. This area was profoundly transformed in the Late Bronze Age with the construction of the

UGARIT. Figure 3. *City rampart, with rear gate and tower above.* (Courtesy Mission Française de Ras Shamra-Ougarit)

Royal Palace. Successive enlargements were also carried out on the fortified gate that protected the palace on the west.

The fortified gate leading only to the royal area did not provide access to the town for its inhabitants or its merchants transporting merchandise from the port. Exploration of a wide depression on the south slope confirmed (1992) the hypothesis of a Main Street that crossed the Nahr ed-Delbeh by way of the bridge-dam (still being excavated). This would have been the principal route leading from the roads on the plain into the interior of the city. Other routes of access were probably used: another bridge was probably located to the north, and to the east, relatively gentle slopes lead toward the terrain cultivated for agriculture.

City Plan. The space delimited by the contour of the mound allowed several occupation zones. About 6 ha (15 acres) were explored on the surface, less than one-third of the tell. One part of the urban area was reserved as the royal domain (the palace zone); it was spread over 10,000 sq m and was isolated architecturally from the rest of the city. The area of the Acropolis revealed two large temples. The remainder of the site consisted of residential areas.

Palace area. The Royal Palace, constructed in several phases (fourteenth–thirteenth centuries BCE), is a spectacular monument in terms of its size (at its maximum 120 m east–west and 90 m north–south; it covers close to 1 ha, or 3 acres) and the quality of its construction (cut stone, rubble, wood, *terre pisé*). Its successive enlargement corresponded to the expansion of royal power and its administration. A dozen stone staircases and a number of walls preserved to the floor of the upper level attest to the existence of at least one upper story. In its final stage, its elaborate floor plan reveals the differentiation of space on several levels: administrative (regulation of the affairs of the realm mingled with those of the palace), public and official, and private.

On the northwest the palace was entered from a paved square that opened onto the fortified gate, entry was through a vestibule with two columns; a vast court (I) then led to the "throne room." Various smaller rooms (guardrooms, administrative offices), with stairways leading to upper floors, yielded deposits of administrative documents and correspondence (the West Archives, Annex Office of Archives).

To the south and east of this official zone, groups of rooms were organized around other courts and rooms (II, IV, VI). The royal tombs were found to the north of court II. Numerous private houses were also found to include a family tomb. The area of court IV and room VI held the Central Archives (juridical texts and royal contracts; from which 135 impressions of dynastic seals permit the reconstruction of the succession of the kings of the fourteenth–twelfth centuries BCE). The grouping around court V, to the south, with its rectangular basin, constituted one of the most recent building efforts; in this area the very important South and Southwest Archives were found that may have fallen from an upper story.

The eastern part of the palace included a large garden (III), onto which private apartments opened: one room (northwest of the garden) yielded luxurious furniture inlaid with ivory (bed panels, a small round table). The rooms to the northeast of the garden yielded the East Archives (economic texts). Several groups of rooms to the north of the

palace were connected to the area: the Arsenal; the Residence of the Military Governor; the Building with Pillars (once wrongly designated by Schaeffer as Stables); and the Hurrian Temple. The palace area carefully bounded and protected from the city by continuous walls and well-defended gates, also boasted elaborate arrangements, restricted to it, for personal hygiene, such as drainage pipes and sewer mains. [*See* Personal Hygiene.]

The administrative and financial texts and lists of villages and crafts lead scholars to believe that royal power was expanded in the course of the thirteenth century BCE (see above). The physical extension of the royal area in relation to the rest of the town and the concentration of the archives found in the palace confirm this conclusion.

Acropolis. The temples on the Acropolis were designated the Temple of Baal (it housed a stela of Baal with a thunderbolt and an Egyptian stela with a dedication to "Baal Saphon") and the Temple of Dagan (its stelae are inscribed in Ugaritic). The Temple of Baal was built in an enclosure. Strong foundations supported a platform upon which the building stood. It was composed of a vestibule reached by a stair on its facade and a larger rectangular room. A monumental interior stairway wound around three sides of the structure, which permits an approximation of its total height at about 18 m. The temple, in the form of a tower, supported a platform on its roof on which certain rituals took place (cf. the mythological text found in 1930 [*CTA* 6; *TO* 1, 480–574], where the king Keret offers a sacrifice "at the top of the tower"). The height of this tower, on an acropolis 20 m above the plain, made it a characteristic element of the landscape and a landmark visible from far at sea. The seventeen stone anchors counted in this temple demonstrate its veneration by sailors. [*See* Anchors.] The quality of the offerings (e.g., gold vessels) indicate the importance of the cult. The Temple of Dagan, of which only the enormous foundations remain, took the same tower form.

Close to the temples isolated in their enclosures, blocks of houses were reached by narrow streets. This quarter was not only a simple middle-level habitation area, for the house known as the House of the Grand Priest or (the Library) is located between the two temples. From 1929 onward it yielded an important collection of bronze weapons and utensils bearing dedications to the "chief of the priests." The inscriptions furnished one of the keys to the decipherment of Ugaritic, and the most important mythological texts were discovered there (*TO* 1).

Residential areas. Ugarit's city plan for the southern part of the mound reveals no regularity. As a result of excavation since 1992, a central axis has begun to appear, coming from the south (Main Street). From the Residential Quarter to the South Acropolis Trench, roughly parallel streets follow the curves of the site's east–west contour approximately; they are connected by short, narrow transverse alleys. These define blocks of varied shapes that lack both an orthogonal pattern and any regularity. This circulation network overlies an older network, created over the course of centuries by the disorderly evolution of a living habitat.

Ugarit's residential areas appeared in various parts of the city: in the Lower City, in housing on the acropolis, in the South Acropolis Trench, and in the Residential Quarter. How the residential areas were organized and their domestic architecture (materials, plans, construction techniques) have been studied recently in several quarters: the South City (*RSO* 10), City center (*RSO* 3), South Center, and Main Street.

In spite of the observations of former excavators, specific districts reserved for craftsmen and a population of elevated rank could not be confirmed. Clear social overlapping appeared: the large houses of the rich, small, simple habitations; and urban craft activities coexisted in the same blocks. The social rank or function of the owners (wealthy merchants, royal officials, representatives of foreign powers) can be deduced from the presence of archives, as in the Residential Quarter (in the Houses of Rasapabu, the Scholar, and Rap'anu, the bronze armorer), South City (House of the Literary Tablets), South Acropolis (House of the Priest-Magician), and South Center (House of Urtenu).

Cult places are identified across the city's habitation areas (religious activities were omnipresent). These sanctuaries integrated into the insulae opened directly onto the public streets or belong to blocks otherwise occupied by residential buildings. Their sacral character is recognizable in their architectural organization (the Rhyton Temple in the City Center) and/or, when the plan of an area is poorly preserved or difficult to interpret, in the furnishings discovered: ceremonial rhytons, cultic furniture, incense burners, statuettes and stelae), and objects tied to the practice of divination such as inscribed liver and lung models. Domestic cults, which are a manifestation of the popular religion, are attested by the number and dispersion across the inhabited areas of small idols (pendants in precious metal, terra-cotta figurines).

It is difficult to estimate the population of the town of Ugarit in the last phase of its history. Texts (financial, mainly) and the size of the houses and their supposed density suggest six thousand to eight thousand inhabitants for the thirteenth-century BCE city, out of twenty-five thousand inhabitants for the whole kingdom. Archaeological indices lead to the belief that the population increased in the course of the thirteenth century; the increase in the density of habitation agrees with what can be inferred from the texts.

Material Culture. Numerous objects, attesting to the technical competence of the craftsmen of Ugarit, reveal strong technical specialization and artistic skill. Craftsmen worked in all sorts of materials: ceramic, stone, ivory, metal, faience. Pottery was mainly of local manufacture. Mycenaean, Cypriot, and Minoan imports constitute statistically a small part of the ceramic repertoire, but the evidence they

provide for international exchanges, the population's tastes, and the transfer of techniques is significant.

Sculpture is represented by several stelae (see figure 4) and stone statues (see figure 5); technical and stylistic analyses demonstrate the existence of local workshops. In the minor arts—molded figurine manufacture, vessel decorating, engraving, ivory carving and glyptic—the artists of Ugarit produced objects for the gods and kings that count among the most accomplished in the LB Levant, including ivory furniture from the Royal Palace and gold cups found on the Acropolis. [*See* Furniture and Furnishings, *article on* Furnishings of the Bronze and Iron Ages; Stelae.] Artistic and intellectual activities, strongly tied to religious concerns, are known from the texts moreso than from archaeology. The musical instruments discovered in the excavations (bronze cymbals, ivory rattles, and a horn) evoke the ceremonies that once produced the ritual texts and mythological recitations. [*See* Musical Instruments.] Literature was supported by a scribal profession. No precise arrangement for a school has yet been recognized, but several abecedaries, lexicographical documents, and student copies prove that students learned to write and that a fraction of the population learned technical vocabulary and foreign languages according to pedagogical techniques.

MARGUERITE YON

Translated from French by Nancy Leinwand

UGARITIC. The Ugaritic language belongs to the West Semitic language group and is probably a late manifestation of one of the Amorite dialects; its phonetic inventory is closest to that of the Old Arabic and Arabian languages. It is the only West Semitic language written in a cuneiform script, alphabetic in character rather than syllabic and apparently invented in the first half of the second millennium BCE, in imitation of alphabetic linear scripts. The language has only been known since 1929, when the first texts were discovered at the site of Ras-Shamra on the north Syrian coast. The script was essentially deciphered within a year by scholars working independently, although subsequent refinements were necessary and minor corrections continue to be made. Texts in the Ugaritic language are presently attested only in the area of Ugarit, but brief and/or fragmentary texts using the Ugaritic writing system are attested from Kamid el-Loz in Phoenicia to Beth-Shemesh in Canaan (Dietrich and Loretz 1988: 205–296).

A vigorous debate was originally waged over the proper assignment of the language within the Semitic language group, with no real consensus ever reached. The historical and linguistic links with the peoples grouped under the general heading "Amorites" makes the description given above plausible, although much more Amorite data is required to demonstrate the link. Paucity of data also impedes the description of relationships with the later West Semitic languages. At this stage it is only possible to say that linguistically the best parallels are with the Arabic and Arabian families of languages, while literally the closest ties are with Hebrew.

The basic writing system, like all the later Northwest Semitic alphabetic systems, is consonantal, with no provision for noting vowels. The reconstruction of the vocalic aspect of the language must rely, therefore, on four types of data: (1) the existence of three *'aleph* signs, a distinctive feature of the Ugaritic alphabet (see below); (2) Ugaritic words in polyglot vocabularies ("dictionaries" written in syllabic script with columns for Sumerian, Akkadian, Hurrian, and Ugaritic); (3) Ugaritic words appearing in Akkadian texts, either alone or as glosses to an Akkadian word; and (4) comparative Semitics.

The language is characterized by a conservative phonology and morphology. The basic alphabet consists of twenty-seven signs (as compared with twenty-two in Phoenician/Hebrew), at the end of which three signs have been added: one sibilant ({š} = no. 30) and two supplementary *'aleph* signs ({å} = no. 1, {î} = no. 28, and {ů} = no. 29). Although the two *'aleph* signs were apparently added in order to give three signs that could be used in the writing of languages that permitted vowel-initial syllables (e.g., Hurrian and Akkadian), the three signs are used in Ugaritic texts in a quasi-syllabic fashion to represent consonant + vowel: {å} = /'a/ or /'ā/; {î} = /'i/, /'ī/, or /'ê/; {ů} = /'u/, /'ū/, or /'ô/). The Ugaritic alphabet has signs for all of the consonantal phonemes known from Arabic, with the exception of /ḏ/, which has shifted to /ṯ/; usage of certain signs, in particular {ḏ} and {ẓ}, however, shows that there is not a perfect match between graphs and phonemes.

Nominal morphology is characterized by a full case system, the productive use of three grammatical numbers (singular, dual, and plural), the retention of the feminine singular ending *-t*, and the absence of a definite article. The most striking features of morphosyntax are the retention of

UGARITIC. *Tablet showing the Ugaritic alphabet.* (Courtesy ASOR Archives)

the case vowel in the construct state (e.g., *ksỉ ṯbth* = */kussa'u ṯibtihu*, "the throne of his dwelling") and the inconsistent use of "chiastic concord" with the numbers 3 through 10 (i.e., a masculine noun is modified by what appears to be a feminine form of the number and vice versa).

The verb system is similar to the other West Semitic systems. Striking characteristics are the use of a Š-causative stem, of which only remnants are found in the later West Semitic languages; infixed- or prefixed-*t* variants, with middle/passive functions, of each of the major transitive stems; the probable existence of an internal passive voice for each of the transitive stems; and a complete set of mood distinctions marked by suffixation in the imperfective system (-ø = jussive, *-u* = indicative, *-a* = volitive, and *-an(na)* = "energic"). The poetic texts preserve the archaic use of a ø-ending *yqtl* preterite.

Because the language is still relatively poorly attested, it is difficult to describe the lexicon in comparative Semitic terms and give proper weight to word classes. Three primary facts are clear: (1) the most basic terms are common Semitic (family terms, geographic terms, and names, etc.); (2) there are many lexical isoglosses with Arabic (though the number would certainly be reduced if there were more Hebrew and Phoenician texts); and (3) the primary verbs of movement (e.g., "walk," "ascend," "descend") are closer to the Phoenician/Hebrew camp than to Aramaic or Arabic—although, as would be expected, Ugaritic has its own peculiarities (e.g., *tbˁ* as the primary verb for "to depart").

For purposes of grammatical and literary analysis, the Ugaritic corpus must be divided into two classes, poetry and prose. Poetry is characterized by an archaic form of the language, particularly in verbal morphosyntax, and is attested only for religious texts. Most of these are major mythological texts dealing with divine society and politics and with relationships between humans and gods. In addition, there are several minor mythological texts, sometimes with a practical application; incantations; a prayer embedded in a prose text; and a funerary ritual—all in poetic form. Prose is used for letters; administrative texts of all types, including contracts; and for religious texts reflecting ritual practice.

Bordreuil, Pierre, and Dennis Pardee. *La trouvaille épigraphique de l'Ougarit,* vol. 1, *Concordance.* Ras Shamra–Ougarit, 5. Paris, 1989. Nearly complete listing of all inscriptions found at Ugarit from 1929 to 1988 and at Ras Ibn Hani from 1977 to 1987, and of inscriptions thought to have come from Ugarit or that are in Ugaritic script. The body is arranged in order of field number and indicates find spot, physical description, and *editio princeps.* There are indices of museum numbers, of first and primary editions, of major text collections, and of find spots. The work's comprehensiveness makes it the simplest means of gaining access to a Ugaritic text and its primary publications; secondary bibliography, however, is not indicated.

Caquot, André, et al. *Textes ougaritiques,* vol. 1, *Mythes et légendes: Introduction, traduction, commentaire.* Littératures Anciennes du Proche-Orient, 7. Paris, 1974. Generally reliable translation of major myths and legends, with introductions and brief commentary in the form of footnotes.

Caquot, André, et al. *Textes ougaritiques,* vol. 2, *Textes religieux, rituels, correspondance: Introduction, traduction, commentaire.* Littératures Anciennes du Proche-Orient, 14. Paris, 1989. Translations of the prose ritual texts, letters, and minor texts with mythological motifs. Same format as the preceding entry.

Cunchillos, Jesús-Luis, and Juan-Pablo Vita. *Banco de datos filológicos semíticos noroccidentales,* part 1, *Datos ugaríticos I: Textos ugaríticos.* Madrid, 1993. The most complete collection of Ugaritic texts to date,

in transcription, with citations of published collations where such exist.

Dietrich, Manfried, and Oswald Loretz. *Die Keilalphabete: Die phönizisch-kanaanäischen und altarabischen Alphabete in Ugarit.* Abhandlungen zur Literatur Alt-Syrien-Palästinas, vol. 1. Münster, 1988. The most complete study of abecedaries, of texts written in Ugaritic scripts containing fewer signs than the standard alphabet, and of texts in Ugaritic script from other sites. The conclusions drawn from connections with the South Arabian alphabet are dubious.

Gordon, Cyrus H. *Ugaritic Textbook: Grammar, Texts in Transliteration, Cuneiform Selections, Glossary, Indices.* Analecta Orientalia, 38. Rome, 1965. Although now outdated, this is the classic work on Ugaritic; the grammar and lexicon are still useful. The 1967 reprint includes a consecutively paginated eight-page supplement.

Herdner, Andrée. *Corpus des tablettes en cunéiformes alphabétiques découverts à Ras Shamra–Ugarit de 1929 à 1939.* Mission de Ras Shamra, vol. 10. Paris, 1963. Definitive edition, with photographs, hand copies, transliterations, and bibliographies, of the texts discovered during the pre–World War II campaigns at Ras-Shamra.

Segert, Stanislav. *A Basic Grammar of the Ugaritic Language with Selected Texts and Glossary.* Berkeley, 1984. Not so complete a tool as Gordon (1965), but the grammatical analysis is more up to date.

Tropper, Josef. "Auf dem Weg zu einer ugaritischen Grammatik." In *Mesopotamia-Ugaritica-Biblica: Festschrift für Kurt Bergerhof zur Vollendung seines 70. Lebensjahres am 7. Mai 1992,* edited by Manfried Dietrich and Oswald Loretz, pp. 471–480. Alter Orient und Altes Testament, vol. 232. Kevelaer and Neukirchen-Vluyn, 1993. Overview, with personal views expressed, of important recent research on Ugaritic grammar.

Whitaker, Richard E. *A Concordance of the Ugaritic Literature.* Cambridge, Mass., 1972. Complete listing of all words attested in Ugaritic texts published though 1969.

UGARIT INSCRIPTIONS. Inscriptions in nine languages and/or writing systems have been found at the site of Ras Shamra, ancient Ugarit. The inscriptions are in Ugaritic, Akkadian, Sumerian, Hurrian, Egyptian, hieroglyphic Hittite, Hittite, Cypro-Minoan, and Phoenician. With the exception of some of the Egyptian inscriptions and the one in Phoenician, most date to the last two centuries of primary occupation at the site (c. 1400–1186 BCE). In addition to these writings from the site's floruit, a number of coins, dating from Alexander to the present, have been found there or in the area (*Ugaritica,* vol. 7, Paris, 1978, pp. 181–185).

Of these languages/scripts the largest corpora belong to Akkadian and Ugaritic. Because the site was abandoned at the end of the Late Bronze Age, with only relatively ephemeral occupations thereafter, one would not expect to find Phoenician inscriptions. Indeed, only one is known, associated with a later occupation, perhaps imported from elsewhere (*TEO* 414 [*TEO* = Bordreuil and Pardee, 1989; see bibliography]). Six objects inscribed with "Cypro-Minoan" characters, in an essentially undeciphered script, were found at the site and a seventh is from the area (*TEO* 418). A single tablet bears an entirely Hittite inscription; another is a trilingual—a Sumerian literary text with Akkadian and Hittite versions; and a third is a bilingual wisdom text in Akkadian and Hittite (*TEO* 422; Laroche, 1968, pp. 769–784). Hieroglyphic Hittite, which is a different language from classical Hittite, is attested by some seven seal inscriptions, including one that is bilingual with Akkadian (*TEO* 418, 422). Approximately one hundred Egyptian inscriptions are mentioned in the excavation inventories (*TEO* 418). Those discovered in the early years received a good deal of publicity, but a comprehensive collection has never been published. They are mostly short dedicatory texts or inscribed scarabs; several consist of only a cartouche.

Hurrian inscriptions were apparently quite numerous at the site, although only fragments remain of many of them (Laroche, 1968, pp. 447–544). Peculiar to Hurrian is that both syllabic writing and the Ugaritic alphabetic system were used to represent it (*TEO* 418, 422). Equally unusual is the mixing of Hurrian and Ugaritic in ritual texts (*TEO* 418), a very different phenomenon from polyglot vocabularies or bilinguals, where one text is the more or less literal translation of the other. Although Sumerian was clearly part of the curriculum of a Levantine scribe in the Late Bronze Age, most of this erudition appears at Ugarit in conjunction with another language, either as the source text of a bilingual—the target language normally being Akkadian—or as one column in multilanguage vocabularies (some monolingual—i.e., Sumerian-only vocabularies exist). The Mesopotamian lexicographic tradition was well known at Ugarit (van Soldt, 1991, 747–753), where a major contribution to the genre was made—namely, the four-language vocabulary list, with columns for Sumerian, Akkadian, Hurrian, and Ugaritic words, all written in syllabic script (Huehnergard, 1987).

The two major languages in everyday use at Ugarit in the Late Bronze Age were the local language, known to modern scholars as Ugaritic, and Akkadian, the international lingua franca of the time. Hundreds of tablets and fragments inscribed in one or the other of these two languages exist. Occasionally, both languages appear on the same text, although this usage is largely limited to Ugaritic administrative texts, where a total may be expressed in syllabic script. This entry will focus on the fact that the form of the Akkadian language in use at Ugarit was peripheral (compared with its attestation in Mesopotamia) and on the distribution of texts written in Akkadian as compared with Ugaritic. [*For fuller general treatments of the two languages, see* Akkadian; Ugaritic.]

Two principal studies have been done in recent years of the Akkadian as written at Ugarit (Huehnergard 1989; van Soldt 1991). These must be used in conjunction with studies of texts in peripheral Akkadian originating from the same general time and area (Alalakh, Tell el-Amarna, and Emar; cf. Mari earlier, and, even earlier, the similar, though linguistically different, situation at Ebla). To date, only the el-Amarna texts have been the object of publications of the same quality as those on Ugarit Akkadian.

The dialectic features of Akkadian can be organized under

two main headings, orthography and grammar. The first has to do with the Sumero-Akkadian syllabic writing, wherein the signs are polyvalent, permitting multiple writings of a given syllable. Local usages developed that can be described and quantified. Grammatical features, on the other hand, may reflect either outside origins and subsequent influences—for example, a Babylonian origin with Assyrian influences—or the effect of the local language on the lingua franca. The last influence is of particular interest, for it can reveal features of the substrate language that the alphabetic writing system does not reveal.

In general, the Akkadian texts from Ugarit are not so severely marked by the local language as is the case with many of the Amarna texts. [*See* Amarna Texts.] Were it not for the polyglot vocabularies, we would have relatively few Ugaritic words attested as glosses in Akkadian texts. Moreover, with the exception of a few lexical usages, the non-normative Akkadian features are for the most part attested in the other western peripheral corpora (Huehnergard, 1989, pp. 283–284).

The use of Ugaritic or Akkadian was decided, broadly speaking, by the intended reader/audience and by the function of the document. Thus, most international correspondence would be in Akkadian, whereas letters between Ugaritians would be in Ugaritic. Nearly one hundred documents are attested in Ugaritic, twice the number in Akkadian, providing a unique opportunity to compare the epistolary genre couched in a local language and in a lingua franca. It is true, of course, that a greater proportion of the Akkadian letters will represent usages of other areas because the tablets would have been sent to Ugarit from abroad (many of the texts edited by Jean Nougayrol in *Palais Royal d'Ugarit,* vol. 4, Paris, 1956, represent international correspondence). The question is open as to whether documents representing international correspondence in Ugaritic are translations or originals (whether the document actually carried to Ugarit was inscribed with one language or the other) and whether a scribe capable of writing Ugaritic would have been, for example, in the Hittite or Tyrian court. All that can be said for certain is that, to date, no doublets have been found—that is, an Akkadian original and a corresponding Ugaritic translation.

Akkadian was preferred for legal texts, not only for those of an international character, such as treaties or tribute lists, but also for those establishing a legally binding situation or marking a change of ownership between parties at Ugarit. Fewer than ten legal texts written in Ugaritic are known to exist, only a fraction of the total existing in Akkadian (much of *Palais Royal d'Ugarit,* vol. 3, published by Nougayrol in 1955, was devoted to land transfers in Akkadian). Most of these legal situations involved the king, either as a party to international agreements or as the highest legal authority at Ugarit—land transfers are usually expressed, fictitiously or not, as having been effected by the king himself ("on this day, King so-and-so has taken the property of $Party_1$ and given it to $Party_2$").

Administrative documents are primarily in Ugaritic, but not exclusively so: nearly nine hundred such documents are known in Ugaritic (including fragments whose classification is not absolutely certain), about a hundred in Akkadian (many of the texts edited by Charles Virolleaud, [vols. 2 and 5] 1957 and 1965, respectively, are administrative texts in Ugaritic, while many of the texts edited by Nougayrol, vol. 6, 1970, are administrative and in Akkadian). The reason for the choice of one language over the other is usually not clear, in no small part because of the laconicity characterizing the genre in both languages. Many of the administrative documents are simple lists, of personal or place names, organized according to various criteria (e.g., personal names organized by occupation or place of origin). Frequently, each name on the list is followed by a number, indicating receipt or donation by this person or place of a certain commodity. The purpose of the document would usually, although not always, have been indicated in the heading of the text itself; unfortunately, the heading is often damaged or missing entirely, with the result that the entities designated by the numbers may be unknown or uncertain.

The distribution of religious and literary texts stands in contrast with the genres previously mentioned by being much more clearly demarcated: all texts reflecting local practice and belief are in Ugaritic; Akkadian is used only for literary texts of Mesopotamian origin (Nougayrol, 1968, pp. 265–319). Thus, the eighty-odd texts of a ritual, divinatory, or incantatory nature are all in Ugaritic, as are the mythological texts dealing with West Semitic deities and heros. Among the Ugaritic texts are several—such as those dealing with misformed births—that might be expected to have a Mesopotamian origin. No immediate source has been found for any of these, however, and the purity of the Ugaritic language, with virtually no trace of translational elements, argues for a long history of the genre in the local language.

The one area where local religious concerns overlap with Mesopotamian erudition is in that of identification of the divinities occurring in the two areas. Two kinds of texts exist in which local deities are identified with divinities known to Mesopotamian religious science. One is the polyglot vocabulary lists, written in syllabic script, where divine names are included alongside common nouns (Nougayrol, 1968, 246–249). The other is the so-called pantheon texts, which consist of simple lists of divine names. Two different such lists are known, each attested in more than one exemplar: they are monolingual, in Ugaritic or syllabic script, arranged in identical order in each language/writing system. One of these lists is attested twice in Ugaritic (RS [Ras Shamra] 1.017, 24.264) and once in syllabic script (RS 20.024). The other list is found in two exemplars but only in syllabic script (RS 26.142, 1992.2004). The ritual character of the lists is proven by an Ugaritic text containing, among other things,

two lists of sacrifices to deities arranged in the same order as that of the two "pantheons." Though the ritual function of the two lists is clear, and though their importance is proven by the multiple exemplars in different writing systems, the meaning of the groupings and of the associated rituals remains unclear.

ULUBURUN, or Great Cape, cape located 8.5 km (about 5 mi.) southeast of Kaş, Turkey (36°08′ N, 29°41′15″ E). In 1982 a Late Bronze Age shipwreck was discovered only 60 m off the east face of Uluburun, 400 m from its tip, by sponge diver Mehmet Çakır. Excavations by the Institute of Nautical Archaeology at Texas A&M University, in 22,413 dives between 1984 and 1994, revealed a unique cargo lost in the late fourteenth century BCE.

The ship lay on a steep slope with its stern at a depth of 44 m and its bow at 52 m, with artifacts tumbled down to 61 m. Built of cedar in the ancient shell-first tradition, with pegged mortise-and-tenon joints holding its planks together and to the keel plank, it was about 15 m long. A fence of wicker is reminiscent of fencing seen on Egyptian depictions of contemporary Syrian ships and of the wicker fence Odysseus constructed to keep the waves out of his vessel (*Odyssey* 5.526).

The cargo consisted mostly of raw materials, items of trade already known to the excavators primarily, and in some instances only, from ancient cuneiform texts or Egyptian tomb paintings. The major cargo was ten tons of Cypriot copper in the form of 318 flat ingots comprising the typical four-handled ingots weighing about 24 kg apiece; nearly identical two-handled ingots (which disprove the questionable notion that four-handled ingots were cast in imitation of dried ox hides); flat, pillow-shaped ingots; and planoconvex discoid "bun" ingots. Nearly a ton of virtually pure tin ingots (the earliest known) in both the four-handled and bun shapes represent the correct ratio, if mixed with the copper, to have formed eleven tons of bronze; the source of the tin is not known.

More than 150 diskoid glass ingots, in cobalt blue, turquoise, and lavender, are likely the *mekku* and *ehlipakku* listed in tablets from Ugarit and el-Amarna as items traded from the Syro-Palestinian coast, and the cakes of "lapis lazuli" and "turquoise" (as opposed to "genuine lapis lazuli" and "genuine turquoise") shown as tribute from Syria in a relief of Thutmosis III at Karnak, Egypt. [*See* Ugarit Inscriptions; Amarna Tablets.] They are the earliest intact glass ingots known. Those of cobalt blue are chemically identical to the blue glass in eighteenth-dynasty Egyptian vases and in Mycenaean pendants, suggesting a common source for all. [*See* Glass.]

Logs of what the Egyptians called ebony, now known as blackwood *(Dalbergia melanoxylon)* from tropical Africa, and of cedar are also unique archaeological finds. A ton of terebinth resin from the *Pistacia atlantica* or *Pistacia terebinthus* tree, known to have grown in the Near East and on the islands of Cyprus and Chios, was carried on the ship in more than one hundred Canaanite amphoras. This is the first scientifically identified find of this substance, which may be the Egyptian *snṯr* brought in Canaanite jars from the Near East to the pharaoh to burn as incense in religious rituals.

Other raw materials include ivory in the form of whole and partial elephant tusks and more than a dozen hippopotamus teeth; murex opercula, a possible ingredient for incense; tortoise carapaces, possibly intended as sound boxes for musical instruments; and ostrich eggshells that were probably intended to be embellished with faience or metal spouts to create exotic canteens.

Manufactured goods were also on board. At least two of ten large pithoi (storage jars) contained Cypriot export pottery, including base-ring II, white slip II, and white-shaved and bucchero wares; lamps; and probably "wall brackets" of unknown purpose. Several faience drinking cups were crafted as the heads of rams or, in one case, a woman. Ca-

ULUBURUN. *Archaeologist Faith Hentschel measures the precise location of a copper oxhide ingot.* (Copyright Frey/INA)

naanite jewelry includes silver bracelets, or anklets, and gold pendants, one with a nude goddess in relief holding gazelles and another with a falcon grasping hooded cobras. A gold goblet is of uncertain origin. Assorted beads are of agate, gold, faience, glass, and Baltic amber. Other artifacts include two duck-shaped ivory cosmetics boxes with hinged-wing lids, copper caldrons and bowls, a trumpet carved from a hippopotamus tooth, and more tin vessels than had previously been found throughout the Bronze Age Near East and Aegean. A stone ceremonial scepter-axe or mace is of a type otherwise known only in the northern Balkans.

Bronze weapons on board include arrowheads, spearheads, daggers, and Canaanite, Mycenaean, and probably Italian swords. Bronze tools include awls, drill bits, a saw, chisels, axes, and adzes. The largest collection of Bronze Age zoomorphic weights includes a sphinx, cows and bulls, lions, ducks, frogs, and a housefly, with one ornate weight bearing the figure of a cowherd kneeling before three of his calves.

Foodstuffs, whether as cargo or for shipboard use, include almonds, figs, olives, grapes (or raisins or wine), black cumin, sumac, coriander, and whole pomegranates, with a few grains of wheat and barley. Lead net sinkers, netting needles, fishhooks, and a bronze trident are evidence of fishing from the ship.

A tentative date of around 1316 BCE for the ship's sinking has been obtained by tree-ring analysis of a log (perhaps cargo, perhaps firewood) that presumably had been freshly cut when the vessel last sailed. This matches the fourteenth century BCE date of the Mycenaean pottery, and the date of a unique gold scarab of Egypt's Queen Nefertiti that could not have been put on board before her time in the middle of that century. The scarab was found near a jeweler's hoard of scrap gold (Canaanite medallions), silver (Canaanite bracelets), and electrum (an Egyptian ring); if it was part of this hoard, the suggestion is that the ship sank after the reign of Nefertiti, at a time when her scarab would have been worthless except for its gold value.

Ascertaining the nationality of the ship is also problematic. Assyrian, Syrian, and Kassite cylinder seals were recovered but do not necessarily mean that there were merchants on board from those lands because collections of seals were commonly sent as tribute or gifts from Near Eastern rulers to both Egyptian and Aegean rulers. Most of the cargo could

have come from the Syro-Palestinian coast and Cyprus, but cargos do not identify the nationality of the ships that carried them either. Stronger evidence of nationality comes from the ship's twenty-four stone anchors. They are of a type virtually unknown in the Aegean but often found in the sea off the coast of Israel. Also found reused as building blocks in temples and tombs in Ugarit, Byblos, and Kition, this type of anchor seems to have been manufactured at Tell Abu Hawam and Tel Nami in Israel. [*See* Abu Hawam, Tell; Nami, Tel; Anchors.] An ivory-hinged boxwood diptych whose interior would have held wax writing surfaces (now missing) was found in a jar of whole pomegranates; parts of other diptychs appeared elsewhere on the site. Although they are of the type mentioned by Homer in his only reference to writing (*Iliad* 6.169), these diptychs are most likely of Near Eastern origin. A partly gold-clad bronze statuette of a female, perhaps the ship's protective deity, is Canaanite. On the other hand, the Mycenaean glass relief beads, bronze pin, spears and knives, tools, eating ware (cups, dipper, flasks, and a pitcher), and a pair of swords and merchant's seals suggest the presence of at least two Mycenaeans on board.

CEMAL PULAK and GEORGE F. BASS

UMAYYAD CALIPHATE. In 661 CE political power shifted away from family of the prophet Muhammad and passed to the descendants of one of the old Quraysh elite families of pre-Islamic Mecca, the Bani Umayya. The first Umayyad caliph, Muʿawiyah, was the son of Abi Sufyan, the pagan leader of Mecca at its submission to Islam in 630. After Byzantine Syria had been conquered by the Muslims, Muʿawiyah, now converted to Islam, was appointed as its governor around 640 with Damascus as his seat, replacing the old Byzantine administrative centers at Caesarea and Bosra.

Muʿawiyah inherited the Greek-based bureaucracy of Syria and Palestine and the Syrian Arab tribal forces, which had formerly defended the old Byzantine desert frontier. These tribes were either Christian or partly converted to Islam initially and they became the military mainstay of the Umayyad regime. In essence, the Umayyads inherited in Syria something of the old Arab Ghassanid federate kingdom that had guarded the eastern frontier of the Byzantine Empire in the sixth century. In his turn, Muʿawiyah protected the interests of the Syrian tribes by deflecting Arab immigrants from the Arabian Peninsula away from Syria to other territories like Iraq or Egypt.

When the third caliph, ʿUthman ibn ʿAffan, was murdered in 656, the prophet Muhammad's son-in-law, ʿAli ibn Abi Talib became caliph. Muʿawiyah, as a senior relative of ʿUthman, emerged as the leading protagonist of those seeking retribution for the murdered ʿUthman, opposing ʿAli's caliphate for his failure to bring the killers to justice. Muʿawiyah's Syrian forces fought ʿAli at Siffin on the Euphrates in north Syria in 657, where it was eventually decided to submit the question of the caliphal succession to arbitration. The negotiations were overtaken when ʿAli was murdered by a discontented Khawarijite in 661 and Muʿawiyah emerged as the only figure able to exercise power, and to establish a caliphate. As a result, political power definitively shifted to Damascus and away from Medina.

Among those who opposed this outcome were the Shiʿat ʿAli, the party of ʿAli, who were strongly represented in al-Kufa. They held that the Imamate or Islamic leadership rightfully belonged in the family of the Prophet and that it should have passed from ʿAli to his son al-Husayn. With the killing by Umayyad forces of al-Husayn at Karbala in 680, an intense sense of wrong was engendered among the Shiʿa,

enhancing their already deep-seated opposition to the Umayyad regime.

At Muʿawiyah's succession in 661, the caliphate reached from the western frontier of Libya to the eastern borders of Iran. During ʿAli's caliphate, the conquests had languished, but they now resumed. The final conquest of North Africa was initiated after the foundation of Qayrawan in 670, which allowed the Muslims to resume their westward advance into the Berber territories of modern Algeria to arrive at the Atlantic by 700. From North Africa, they initiated the conquest of Spain in 710–711, which ended with a deep raid as far as Poitiers near Paris in 732. Meanwhile, the Umayyads also resumed raids into Byzantine Asia Minor, which culminated in the unsuccessful siege of Constantinople in 674–680.

Little remains of monuments built by Muʿawiyah: a dam at al-Ta'if in the Hijaz has an inscription in his name dated AH 58/677–678 CE, presaging the interest of later Umayyads in irrigation. A description dated to 670 CE of the mosque of al-Aqṣa at Jerusalem—a rough building of reused columns able to accommodate a congregation of three thousand—probably records Muʿawiyah's work. Nothing remains of Muʿawiyah's palace at Damascus, the Qubbat al-Khadhra, although it presumably related in some degree to excavated Umayyad urban palaces at al-Kufah, Jerusalem and Amman. The excavations of the palace at al-Kufah, possibly built by the Umayyad governor Ziyad ibn Abihi, show a plan derived from Sasanian forms, with emphasis on the hierarchical position of the governor in formal audience in the palace. This eastern formula found its way thereafter into later Umayyad palaces and eventually into the ʿAbbasid palaces of Baghdad and Samarra.

After the death of Muʿawiyah in 680, the succession of his son Yazid was not recognized by ʿAli's son al-Husayn or by ʿAbd Allah ibn al-Zubayr. The latter was descended from the ʿAbd al-ʿUzza branch of Quraysh and his mother was the daughter of Abu Bakr, the first caliph: his aunt was ʿA'isha, the Prophet's favorite wife. When Husayn was murdered at Karbala by Umayyad forces, Ibn al-Zubayr announced himself as caliph at Mecca, feeling secure in his strong connections with the Prophet's family. His rebellion was initially successful, and al-Kufah, Egypt, and parts of Arabia and Syria all adhered to his cause. Meanwhile, the Umayyad succession passed to ʿAbd al-Malik of the Marwanid branch of the family, and for over a decade there were two claimants to the caliphate, the one based in Mecca, and the Umayyad candidate in Syria. In the end, the military strength of the Umayyads won out and their hegemony was restored after besieging Mecca and killing Ibn al-Zubayr.

The victory of ʿAbd al-Malik over Ibn al-Zubayr marks the reunification of the caliphate and the beginning of the reconsolidation of the state: in about 695, the administrative system was reformed. Arabic became the official language of the administration, replacing Greek and Pahlavi. The coinage was also reformed, and a purely Islamic coinage was instituted. It was so successful that it set the basic formula of Islamic coinage for centuries thereafter.

Even before the defeat of Ibn al-Zubayr, ʿAbd al-Malik had begun to develop the Ḥaram esh-Sharif enclosure at Jerusalem, the major holy site under his jurisdiction during the civil war. The only Islamic monument in Jerusalem before his day was the rough al-Aqṣa structure already described. North of it, ʿAbd al-Malik built the Dome of the Rock, a great octagon constructed over a natural rocky outcrop, and surmounted by a gold dome. Its formal origins lay in commemorative and celebratory buildings of the Byzantine period, including the Anastasis (327–335), the Church of the Ascension (c. 378), and the Tomb of the Virgin (fifth century), all at Jerusalem. [*See* Jerusalem.]

The Dome of the Rock was decorated on the exterior and interior with mosaics showing Qur'anic inscriptions with foliage and Sasanian-style crowns. It has been interpreted variously as a monument to the victory of Islam over the other monotheistic religions, and a reference to the Islamic paradise. The decoration would be more readily understandable had Palestinian churches of the Byzantine period survived intact, but even without them, it seems clear that the Dome of the Rock is a product of the islamization of the iconography and architecture of the eastern Mediterranean that had already been the common source of both Christian and Judaic decoration in the Near East.

In the early years of the 8th century, the Umayyads embarked on a series of territorial expansions. As Muslim power was being projected westward to Spain, raids across the Byzantine frontier culminated in the last great Umayyad siege of Constantinople in 716–717. Al-Hajjaj, their vigorous governor in the east (al-Mashriq), founded al-Wasit in Iraq in 702–705 as an administrative town from which he governed Iran and Khurasan. When the Muslim forces resumed their eastward conquests, they advanced beyond the old Sasanian borders towards the Iranian and Turkic lands of Transoxiana (Ma wara nahr) in Central Asia. At the same time the Muslims carried their advance as far as Sind (modern Pakistan) in India where a mosque has been excavated at Banbhore, dated to in 727–728.

The wealth deriving from these conquests coincides with the foundation by the first Marwanids of a series of major new Islamic buildings, almost all mosques. These provided the community with monuments comparable with the great imperial Byzantine monuments in the Near East. Al-Walid I completed al-Aqsa at Jerusalem as well as the palace at Jerusalem in a program of extravagant grandeur that had been initiated by his father, ʿAbd al-Malik. This included the Ḥaram Mosque at Mecca; the Great Mosque of Sanʿa in Yemen with materials from the sixth century cathedral, and the Mosque of ʿAmr at al-Fustat, which was covered with mosaics.

The Prophet's mosque at Medina (707–709) was also expanded to incorporate the tombs of the Prophet and the first

two caliphs. The walls were clad with marble paneling and wall mosaics showing trees and buildings, although nothing of this scheme, survives. The only indications of the quality of these lost decorations is preserved in the contemporary mosaics of the Great Mosque of Damascus which al-Walid I also enlarged and lavishly decorated with marble, gold leaf, and glass wall mosaics, with a river, trees and architecture.

The architectural motif that is so significant in the Medina and Damascus mosaics was an inheritance from Late Antique imagery in which it was used in geographical contexts and as a general honorific frame for apostles, saints, and books of the Gospels. Adapted to an Islamic context, the same element of honor persists, so that a Qur'an of Umayyad date found at San'a also has an architectural frontispiece. Likewise, a series of stylized columns and arches appear in chapter headings of an Umayyad Qur'an found in the mosque of 'Amr ibn al-'Aṣ at al-Fustat: the process at work in all these cases is that of adapting pre-Islamic subject matter to Islamic purposes.

The Arabic sources vary as to the authors of the Umayyad mosaics. It is said that Byzantine craftsmen participated in the decoration of the Prophet's mosque at Medina although it is also suggested that the craftsmen were Syrian and Egyptian craftsmen from within the caliphate. The wall mosaics of the churches of the pre-Islamic Near East are almost entirely lost, and very little pre-Islamic painting survives either, although both must have been more influential on Umayyad art than we can ever know. However, the discovery of sophisticated pre-Islamic paintings at Qaryat al-Fau in Saudi Arabia and at Shabwa in Yemen suggests that there may have been an Arabian antecedent for the Umayyads' taste for mural decoration. [*See* Qaryat al-Fau; Shabwa.]

The mosaics at the Dome of the Rock and the Great Mosque of Damascus are the earliest surviving Umayyad religious decorations. Their carefully selected content suggests the existence of some element in Islamic society self-conscious of Islam's need to present its credo visually and to be able to select motifs that conveyed the religious beliefs of the Muslims. They relentlessly excluded representations of living beings, relying on nonfigurative motifs drawn from Byzantine and Sasanian traditions, and Qur'anic inscriptions in Kufic script. This formative process created an Islamic artistic vocabulary, appropriate to the most important religious monuments of the caliphate. However, no true synthesis can be said to have been achieved at this stage, and there is no coherent Umayyad "style" as there was a century or more later under the 'Abbasids.

Knowledge of Umayyad urban settlements has greatly increased since the 1980s. Umayyad secular architecture was once most familiar from the palatial buildings in the countryside and on the desert margins of Jordan and Syria. These must still be regarded as a very important part of the Umayyad architectural record, reflecting taste, self-image and the interests of the Umayyad aristocratic elite, and a major means for understanding Umayyad society, but they should also be seen in context of a far broader pattern of settlement and building in the towns and villages of the region.

A distortion in our understanding of the evidence also deserves comment. Jordan is exceptionally well documented archaeologically for this period when richer areas like Palestine, Syria, and Iraq are less well-understood. The same is still more true of Arabia. This distortion may thus give overly great emphasis to Jordan and its monuments.

Towns like Caesarea, Jerash, Beisan (Beth-Shean) and Umm el-Jimal have been excavated, and they show that settlement continued unbroken from Roman and Byzantine times into the early Islamic period, although particular buildings often underwent a change of use, were adapted, or were built anew. This pattern was probably common in many of the old established towns of Palestine and Syria. Faced with a vital economy, the Umayyads seem to have been careful to avoid disrupting the existing settlements in Syria and Palestine. [*See* Caesarea; Jerash; Beth-Shean; *and* Umm el-Jimal.]

Umayyad palaces in the major urban centers are better known today since the excavations at the Qala' at Amman, the palace at Jerusalem adjacent to al-Aqsa, and the palace at al-Kufa. Of these sites, the Amman citadel is the best understood: it stands within the old Roman fortifications of Jebal al-Qal'a, overlooking Amman. It has a formal reception hall that reveals a strong Sasanian element in its decoration and design, conforming to a general tendency to adopt Sasanian imperial forms which is marked in the later Umayyad period.

Apart from these buildings, major lost Umayyad urban palaces include Mu'awiyah's Qubbat al-Khadra' at Damascus, and the palaces at al-Wasit, al-Fustat, and Ramla, founded as the local government center in Palestine by Sulayman ibn 'Abd al-Malik around 715, when Umayyad attention to Jerusalem was waning: it is still largely unstudied.

No single explanation accounts for the numerous Umayyad rural sites, and many of them probably served a variety of purposes. Some were probably related to the need to retain contact with important tribal leaders who were the mainstay of the military forces holding together the vast Umayyad Empire. Some sites seem to have presaged the caravanserais of later Islamic times. Qaṣr al-Kharana (ca 710) and Qaṣr al-Tuba (743–744) in the Jordanian desert seem to have fulfilled this role, and there are buildings at Qaṣr al-Ḥayr al-Gharbi and Qaṣr al-Ḥayr ash-Sharqi, which have also been described as *khans* or caravanserais. [*See* Qaṣr al-Ḥayr al-Gharbi; Qaṣr al-Ḥayr ash-Sharqi.]

Some of these rural buildings suggest a peripatetic Umayyad monarchy, as the princes of the ruling house moved from residence to residence according to season and need. Some places like Khirbat al-Minya and Khirbat al-Mafjar in Palestine were too hot to live in comfortably in summer but would have been clement in winter. The peripatetic nature

of the Umayyads also shows itself in the shifting seat of the caliphate. Although Damascus was Muʿawiyah's seat, and he seems to have built nothing in the desert, he would camp in the *bādi ya* where the later Umayyad palaces of al-Muwaqqar, Qastal, and al-Meshatta were eventually built. Later, Sulayman developed Ramla in Palestine, Yazid II lived at Muwaqqar and Beit Ras in Jordan, and Hisham lived on the Euphrates at Rusafa. The last Umayyad caliph, Marwan II, chose to live at Harran (now in southern Turkey). [*See* Mafjar, Khirbat al-; Qaṣr al-Meshatta; Ramla; Beit Ras; *and* Rusafa.]

The finest of the late Umayyad palaces are marked by lavish extravagance, especially those associated with Hisham and al-Walid II. After the assassination of al-Walid II in 744, his successor was forced to abjure extravagant building projects and the failure to complete al-Meshatta and al-Tuba has been taken as a consequence of al-Walid's fall.

There is a marked concentration of these palatial buildings in the countryside of Jordan, Palestine, and Syria, reflecting the Umayyads' attachment to these districts. The distribution of many of their rural foundations suggests that they were sited in relation to particular roads: Qaṣr Burquʿ, Khirbet al-Bayda', and Qaṣr Jabal Usays are located along a desert road from north Arabia through the Wadi es-Sirḥan to central Syria. Qaṣr al-Tuba of al-Walid II in eastern Jordan lies on a route from Tayma' and the Sirḥan. Al-Qastal, al-Muwaqqar, and al-Meshatta are located on the more westerly route between Amman and the Hijaz, the preferred pilgrim road from Syria throughout the Islamic period. Khirbat al-Minya near Tiberias is close to the road from Damascus to Ramla and Minya, which was still a halt on the official postal route (barid) in the thirteenth century, and Khirbat al-Mafjar (c. 735) near Jericho is close to the road from Amman to Jerusalem.

Qaṣr al-Ḥayr al-Gharbi, Qaṣr al-Ḥayr ash-Sharqi, and Khirbat al-Mafjar preserve evidence of large-scale irrigation systems installed to serve their surrounding agricultural estates and these palaces have been compared to Roman latifundia. At both Khirbat al-Mafjar and Qaṣr al-Ḥayr al-Gharbi, there is decorative imagery that reflects the agricultural character of the estates amidst which these palaces stood. Thus, al-Mafjar, the floor mosaics of the vast bath-hall include a representation of an *ethrog* and a *lulab*, Jewish symbols of the harvest that are found in Palestinian synagogue mosaics. At Qaṣr al-Ḥayr al-Gharbi, one of the great floor paintings shows a Greek earth goddess, Gaia, holding a cloth full of fruit, abundance appropriate to an agricultural estate.

At other sites, the agricultural element is less pronounced or absent altogether. Qaṣr al-Ḥallabat in northern Jordan is attributed to Hisham and was one of several buildings which were formerly Roman *limes* (border) fortresses. Ḥallabat was reconstructed as a palace, with a limited area of field terracing. However, numerous representations of prey in its floor mosaics suggest that a major activity of its residents was hunting. Ḥallabat is also an interesting example of the way in which the old Roman defense line on the desert was made redundant by Islam's creation of a border-free territory from the Indian Ocean to north Syria, for the first time since the fall of the Nabateans in the second century CE.

As the decorative scheme of the Ḥallabat mosaics imply, hunting was a favored pastime of the aristocracy, just as it had been with the Romans, the Byzantines, and the Sasanians. It was also a significant aspect of life and art in pre-Islamic Arabia where hunting may have had a sacred character. The chase is also represented in the desert bathhouse of Quṣayr ʿAmra and at Qaṣr al-Ḥayr al-Gharbi, the latter in a style derived from Sasanian imagery. It is a clear enough indication of the importance of the chase to the Umayyads. [*See* Qaṣr al-Ḥallabat; Quṣayr ʿAmra.]

Umayyad paintings, sculptures and mosaics show a remarkable diversity and it is clear that the Umayyads had no reluctance to include representations of living beings as long as the context was not religious in character. There is also a persistent desire to show Umayyad princes in the context of the standard royal imagery of the period—the six kings of the world at Quṣayr ʿAmra, in a standard Byzantine formula; or the plaster sculptures of Hisham in Sasanian garb that stood over the exterior doorways at al-Mafjar and Qaṣr al-Ḥayr al-Gharbi. Hisham's concern with the appearance of Sasanian royalty was also demonstrated in his interest in a volume of representations of past Sasanian princes and their dress, reflecting growing preference for Sasanian models in the later Umayyad period.

The death of Hisham in 743 marks the beginning of a period of turbulence that finally culminated in the collapse of the Umayyad regime in 750. As tensions between Umayyad factions undermined the strength of the regime from within, the effort of ruling the caliphate through the overstretched Syrian tribal forces at their disposal finally became too much. Those excluded from power by the regime and its supporters increasingly showed their resentment in Islam-inspired insurrection against the government. The Shiʿa especially had never been reconciled to Umayyad rule, and others felt excluded from power by an Umayyad monopoly. A series of rebellions gave expression to these sentiments, culminating in an uprising in Khurasan in the name of the ʿAbbasid family, whose claim to rule was rooted in their descent from the Prophet's uncle, al-ʿAbbas. Leading a coalition of anti-Umayyad forces, the ʿAbbasids defeated the Umayyad armies in Khurasan and advanced on northern Syria and Egypt, where the last Umayyad caliph, Marwan II, was killed in the Faiyum. The Umayyad clan was massacred and replaced by an ʿAbbasid caliphate that avoided Syria and its hostility toward them. Instead, they made Iraq their seat of government, where the center of gravity in terms of the economy and population had already shifted, and this was reflected in the foundation of Baghdad in 762.

The 'Abbasids' caliphate was a far more centralized state than that of the Umayyads. The 'Abbasids emphasized their religious claims to hold the office of caliph, where the Umayyads had emphasized their family's prestige and lineage in terms more tribal than Islamic. However, caution must always be exercised in any interpretation of the Umayyads' intentions, as the historical sources for the period are provided principally by authors working under the hostile 'Abbasids, ensuring that the Umayyads were presented in the worst of irreligious lights. The Umayyad monuments are thus especially important as sources which generally eluded the 'Abbasid interpolation of the record.

After their fall, sympathy for Umayyad claimants persisted in Syria but the country itself became a backwater, eclipsed by Iraq and Egypt, and it only reemerged to prominence in the twelfth century under the Zangids and Ayyubids. However, in Spain an Umayyad regime continued, refounded with emigré Syrian support in 755 at Cordoba by 'Abd al-Rahman I (a grandson of Hisham), who had escaped the massacre of his relations. Secure in their Spanish exile, the Umayyads were to enjoy a quite extraordinary efflorescence, which endured until the early eleventh century.

G. R. D. KING

'UMEIRI, TELL EL-, site located near the southern extent of the hilly region surrounding Amman, Jordan (about 15 km, or 9 mi., south of it), on the northern boundary of the Madaba plain, between the Amman National Park and the Queen Alia International Airport Highway (just to its west), 12 km (7 mi.) northeast of Tell Ḥesban (map reference 1420 × 2324). Across the highway to the east is Tell el-'Umeiri East and just to its north, Tell el-'Umeiri North. The three tells grew up around a perennial spring.

In the nineteenth century, among the explorers who visited the region of Tell el-'Umeiri was Charles Warren, for the Palestine Exploration Fund (PEF), in 1867. He noted that *Amary* was the name of the district, as well as three ruins in it. Claude R. Conder (also for the PEF), while unable to locate the spring, also referred to the three tells in connection with "el-Ameireh." Most explorers, however, bypassed the region, probably because it was not (until recently) near a main thoroughfare and because the other hills surrounding 'Umeiri obscured its importance. Motivated by a desire to discover the ancient borders of Ammon, four German scholars explored the region to the west (Gese in 1958), southwest (Hentschke in 1960; Fohrer in 1961), and south (Reventlow in 1963) of Amman in the late 1950s and early 1960s. Among their discoveries was a series of boundary forts they believed represented ancient Ammon's western border. [*See* Ammon.] Typically, these forts consisted of a rectangular building with an adjacent watchtower; most of these sites are now thought to be farmsteads rather than defense installations. [*See* Farmsteads.]

The first substantive description of the site resulted from the Ḥesban hinterland survey of 1976 (Ibach, 1987). Tell el-'Umeiri West, site 149, was noted as a major site of 16 acres with a spring, considerable evidence of architecture, and huge quantities of sherds. The sherds ranged from the Chalcolithic through Iron Age II periods, with most intervening periods represented. Tell el-'Umeiri East, site 150, was described as a medium site with even more visible architecture, caves, and cisterns; its pottery ranged from the Iron Age through the Umayyad period and included the Roman and Byzantine periods. A third site was noted to the north that contained mainly Mamluk ruins. K. Von Rabenau (1978) appears only to have been concerned with site 150. During a two-month survey in 1979, Franken, with four others, completed the most thorough investigation to that date. Franken concluded that the tell and the surrounding area appeared to reflect almost all of the country's cultural history (Franken and Abujaber, 1989, p. 1). Dividing his findings into four "cycles" (Neolithic–Early Bronze, Middle Bronze–Iron Age, Roman–Islamic, 1850–the present), he advocated urgent investigation. Finally, Abujaber (1984), one of 'Umeiri's landowners, completed his own research on the development of agriculture in the region during the nineteenth century CE, a development to which his own forebears had contributed substantially.

After 'Umeiri's rediscovery by the Ḥesban survey, but before its excavation, Donald Redford visited the 'Umeiri region in 1981 for a three-week survey of sites in Transjordan in which he sought to identify nos. 89–101 of Thutmosis III's list of Asiatic toponyms. After sherding Tell el-'Umeiri West and studying its topography, he concluded that it fulfilled the criteria for nos. 95–96 on the list: its perennial spring was the largest in the vicinity, it had been occupied in the Middle/Late Bronze Age, and it was strategically located. "The evidence thus seems strong *'yn/krmn,* or the Abel Keramim of the Bible (*Jgs.* 11:33), is indeed to be sought at the site of 'Umeiri West" (Redford, 1982, pp. 69–70).

'Umeiri West was excavated by Larry G. Herr as part of the ongoing Madaba Plains Project, directed by Lawrence T. Geraty for a consortium of institutions (Andrews University, together with Canadian Union College, La Sierra University, and Walla Walla College), for five seasons to date (1984–1994). 'Umeiri West is the best-preserved Early Iron I city (c. 1200 BCE) so far uncovered in Jordan. It was fortified by a dry moat cut out of the bedrock at the bottom of the site's western slope. A retaining wall held back a massive rampart running up the slope to the fortification wall. This wall comprised two parallel walls with cross walls in a casemate plan. This is the largest, most coherent defensive system in Palestine from the Early Iron I period. These defenses were built on top of those of the MB IIC period, which also produced a rampart. That city has not yet been reached. An earthquake at the beginning of Iron I split the bedrock underlying the rampart and causing the MB rampart to erode. The Iron I inhabitants rapidly rebuilt the rampart.

In the casemate rooms, beneath 1.5 m of fallen and burned mud bricks, storerooms with flagstone floors contained the fragments of approximately forty collared pithoi: some were lined against the walls, others had fallen from the building's second story. Mixed with the vessel fragments were the charred bones of at least two humans, an old man (based on worn teeth and large bone structure) and a young person. An enemy had apparently thrown spears (five bronze lance and spearpoints were found in one of the rooms) and slingstones into the city and then set fire to it, killing the old man and his younger compatriot who had

been on the upper floor of the house. In the same area fragments of an alabaster vessel were found. Some archaeologists suggest that the city may have been destroyed by the arrival of the Ammonites, whose kingdom gave its name to the modern city, Amman. [*See* Amman.]

Many of the walls of neighboring structures are preserved to a height of more than 2 m by destruction debris, which hid them from sight for more than three thousand years. East of one of the casemate rooms and connected to it by a doorway was a large pillared room. Six pillar bases have so far been uncovered, on top of which wooden posts probably held up the roof. A substantial doorway led through a thick wall separating the structures to other rooms on the east. Beneath this door were the remains of an earlier phase. Unfortunately, the stones in the walls were burned so severely that many are cracked and some of the walls are in danger of collapse (although one stands about 3 m high). Most of the floors are paved with flagstones, but very few objects were found on them. A cultic standing stone was found in 1992 by the Madaba Plains Project. They also removed a plastered pool used by the site's Jewish inhabitants as a ritual cleansing pool in the Roman period (many parallels for the pool can be found from this same period in Jerusalem surrounding the Temple and elsewhere in Israel). [*See* Ritual Baths.]

The excavation exposed the top of the Iron I destruction layer but did not proceed farther. No less significant for the history of Jordan are the thick walls of the imperial Persian administrative center on the southwest of the site. Although the main floors were destroyed by erosion and the basement floors have not yet been reached, the finds—many figurines and approximately forty seals and seal impressions bearing the names and identity symbols of official bureaucrats—indicate the building's importance. (The most dramatic find is the so-called Baalis seal impression, found in 1984; cf. *Jer.* 40:14.) [*See* Seals.] Most of the impressions are of poor quality, with only scratches on their sandstone faces, but several preserve the names and titles of officials of the Late Ammonite monarchy and the treasurers or governors of the Persian province of Ammon (c. 500 BCE). The bureaucrats working in these buildings, and living in the houses immediately to the north, administered and supported a series of agricultural estates surrounding Tell el-ʿUmeiri, from Jawa in the east to Naʿur in the west. [*See* Jawa.] They seem to have produced wine to export in lieu of taxes to their Babylonian and Persian overlords.

The Hesban survey (within a 5-km, or 3-mi., radius of ʿUmeiri) discovered more than one hundred sites, ranging from roads and winepresses to limekilns, farmsteads, watchtowers and forts, and towns. A picture of complex farming systems is emerging from this study that seems to emphasize grain and fruit (especially grape) cultivation. Agricultural technologies included the use of dams and embankments along the valley bottoms to retard erosion and maintain groundwater for successful dry farming. The discovery of cave dwellings with animal corrals from the last few centuries assisted in understanding the way nomadic populations lived in the region during periods of urban growth and decline. [*See* Viticulture; Irrigation; Pastoral Nomadism.] Excavation has taken place as well at Rujm Selim, a large agricultural complex; Al Dreijat, an Iron Age fortress; Khirbet Rufeisah, with unusual Early Arabic inscriptions in a cave/cistern; a nearby Late Iron II rural complex; and, on the slopes of ʿUmeiri, an EB IB megalithic burial (dolmen), an EB IV "cemetery," and an MB IIC cave-tomb. Surveys were also conducted of ʿUmeiri East and ʿUmeiri North, and a random square survey was begun in the territory around Jalul.

LAWRENCE T. GERATY

UMM EL-BIYARA, mountain at the center of the city of Petra, in Jordan (30°21′ N, 35°25′ E; map reference 191 × 970), rising 300 m from the valley floor. The ancient site is on the mountain's flat, trapezoidal summit, approximately

5.5 hectares (14 acres) in area. Occupation has been dated to the Iron II (Edomite) and Nabatean periods. Other Iron II mountaintop sites in the vicinity are Umm el-Ala, Ba'ja III, and Jebal al-Kser; the Iron II site of Tawilan is also nearby. [*See* Tawilan.]

Iron Age pottery associated with walls and foundations was first collected on the surface of Umm el-Biyara by George Horsfield and Agnes Conway in 1929 ("Sela-Petra, the Rock, of Edom and Nabatene," *Quarterly of the Department of Antiquities of Palestine* 7 [1938]: 1–42; 9 [1941]: 105–204). Nelson Glueck was the first to undertake soundings there (1933–1934), collaborating with Horsfield in 1933 (Nelson Glueck, "Further Explorations in Eastern Palestine," *Bulletin of the American Schools of Oriental Research* 51 [1933]: 13–14). As a result of his work, Glueck equated Umm el-Biyara with biblical Sela in the time of Amaziah of Judah (c. 796–781 BCE). In 1955, William H. Morton carried out additional soundings. He found "Edomite" pottery associated with jumbles of stone blocks but no evidence of walls ("Umm el-Biyara," *Biblical Archaeologist* 19 [1956]: 26–36).

Crystal-M. Bennett excavated at Umm el-Biyara in 1960, 1963, and 1965, revealing less than one-third of the site. She found an unfortified Iron Age settlement consisting of a group of houses with long corridor rooms from which small square rooms projected. The houses were built of sandstone, which breaks naturally into flat slabs. In the main part of the excavation the houses were built against a single long wall that ran the length of the excavated area. Similar longhouses are known at the contemporary nearby mountaintop site of Umm el-Ala and may reflect the paucity of timber for roofing.

Settlement at Umm el-Biyara was evidently domestic, judging from the quantity of loom weights and spindle whorls recovered. Buildings were mostly constructed directly on the bedrock. A large number of deep cisterns were found cut into the summit, presumably the water supply, but it is not clear whether they are Edomite or Nabatean. The pottery shows characteristic Iron II shapes, although, unlike assemblages at other Edomite sites, such as Buṣeirah, Tawilan, and Ghrareh, it was unpainted. [*See* Buṣeirah.] The difference may be related to chronological factors, with unpainted pottery probably dating earlier, or to site location, with remote mountaintop sites not influenced by the painted ceramic traditions of Edom. The settlement's main area was destroyed by a fire. Although Bennett found sherds in post-occupation levels that may be Hellenistic, it is likely that settlement took place only in the Iron Age (seventh–sixth centuries BCE).

Bennett's two main objectives were to verify or disprove the identification of Umm el-Biyara with biblical Sela and to obtain a group of stratified "Edomite" pottery. In fact, neither was fulfilled. Umm el-Biyara is essentially a one-period site whose sequence of occupation, destruction (and a final occupation in one area), abandonment, and collapse lacks sufficient stratification to enable the development of a pottery sequence.

An absolute date was provided by a clay seal impression discovered in one of the rooms. Its inscription has been restored as "Qos-Gabr, King of Edom," who is mentioned

UMM EL-BIYARA. *View of the mountain from the Petra valley floor.* (Courtesy P. Bienkowski)

twice in Assyrian inscriptions of Esarhaddon and Ashurbanipal, in contexts dated between 673 and 667 BCE. This seventh-century date is the only absolute date available for Edom, and the dating of all Edomite sites and their associated material is still largely dependent on this seal impression. There was no occupation that could be dated to the period of Amaziah (early eighth century BCE). It is now generally accepted that Umm el-Biyara should not be identified with biblical Sela. Another possible candidate is modern Sela, near Buṣeirah in northern Edom, an isolated prominence with evidence of Edomite and Nabatean occupations (Stephen Hart, "Sela': The Rock of Edom?" *Palestine Exploration Quarterly* 118 [1986]: 91–95; Manfred Lindner, "Edom Outside the Famous Excavations: Evidence from Surveys in the Greater Petra Area," in *Early Edom and Moab: The Beginning of the Iron Age in Southern Jordan,* edited by Piotr Bienkowski, Sheffield, 1992, pp. 143–144).

Bennett's excavations deliberately did not extend to the Nabatean remains on Umm el-Biyara. There is a Nabatean temple on the edge of the plateau, perhaps the reason for the construction of the (ceremonial?) stairway leading to the summit, including a massive ramp that turns through 180 degrees on its way up the slope. At the base of the mountain characteristic Nabatean facades are carved into the rock. None of the Nabatean remains on Umm el-Biyara have been excavated, so their precise date is unknown.

PIOTR BIENKOWSKI

UMM EL-JIMAL, an extensive rural settlement constructed of black basalt in the lava lands east of Mafraq, a seventy-minute drive northeast of Amman, Jordan (39°19′ N, 36°22′ E). One of the largest and most spectacular archaeological sites in Jordan, Umm el-Jimal is located on the edge of a series of volcanically formed basalt flows that slope down from the Jebel al-Druze, a mountain 50 km (31 mi.) to the northeast. This sloping black bedrock provided ancient Umm el-Jimal with two basic resources: stone for constructing sturdy houses and water for drinking and agriculture. The ancient name of the site is not known. David L. Kennedy has argued convincingly that Thantia, Howard C. Butler's suggested name (see below), is better located to the west on the Via Nova (Kennedy and Riley, 1982, pp. 148–152). Henry I. MacAdam (1986) has put forward Surattha, from Ptolemy's *Geography,* as an alternative.

What survives aboveground is an amazingly well-preserved Byzantine/Early Islamic town nearly a kilometer long and a half-kilometer wide, with 150 buildings standing one to three stories high and several towers up to five and six stories. The site's dramatic skyline of somber stone at first gives the impression of a bombed-out modern town. Only close up does it become apparent that this is not a modern war casualty, but an agglomerate of fifteen-hundred-year-old ruins. Inside, the visitor is plunged into a scene of eerie beauty. Walls run in every direction, without apparent plan or order. Neatly stacked courses of stone protrude from a mad confusion of tumbled upper stories. The blue-gray basalt everywhere gives a somber and cool sense of shadow that belies the blaze of bright desert sun. Here and there pinnacles of wall extend their fingers of cantilevered roofing beams to create gravity-defying silhouettes against the cloudless sky. Doorways and alleys lead from room to room and building to building. Large private houses predominate, but there are also fifteen churches from the sixth and seventh centuries, a praetorium, a barrack, gates, and numerous reservoirs.

Umm el-Jimal became known to travelers in the mid-nineteenth century, but the first major work there was done by the Princeton University Expedition to Southern Syria in 1905 and 1909, directed by Butler. Butler (1913) published a list of early visitors to the site who had recorded their impressions. It was first reached in 1857 by Cyril Graham, who published a brief description of the ruins the following year. In 1861–1862 William H. Waddington copied several inscriptions and, more than a decade later, Charles Doughty passed through the ruined city. At about the same time Selah Merrill, then the American consul in Jerusalem, visited it. Gottlieb Schumacher published the first architectural plans, of a church and the city gates, in 1894. In 1901 René Dussaud and Frederic Macler copied several inscriptions. [*See the biographies of Butler, Merrill, Schumacher, and Dussaud.*]

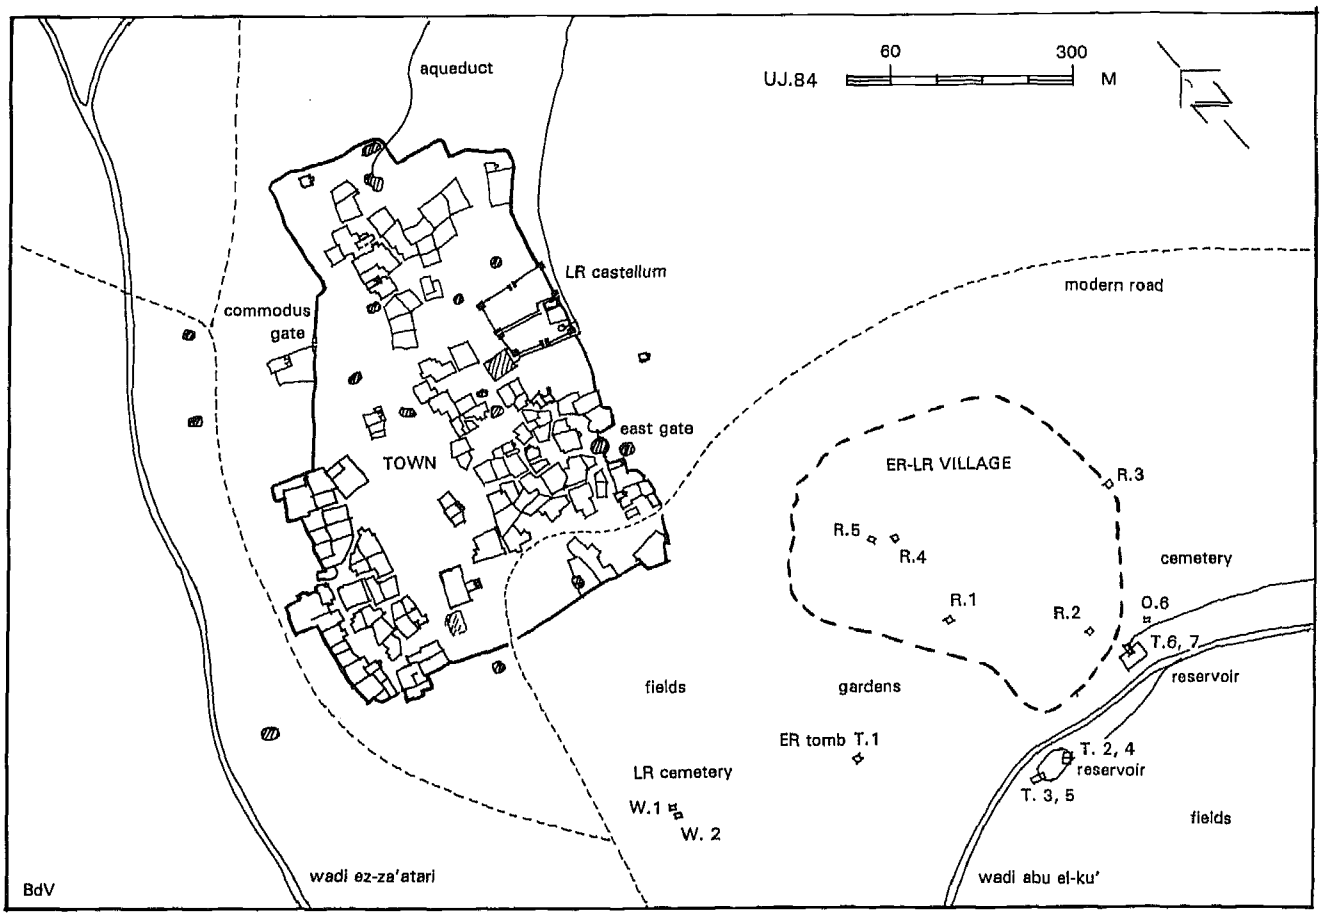
In winter 1904–1905, Butler's team made the first site map, which included public buildings: the praetorium, barracks, 15 churches, reservoirs, gates, 20 houses, and monumental tombs. He published it with an excellent text and restored plans of typical buildings (Butler, 1913). Enno Littmann cataloged numerous Greek, Latin, Nabatean, Safaitic, and Arabic inscriptions (Littmann et al., 1913). George Horsfield published early aerial photographs (Horsfield, 1937), and Nelson Glueck included Umm el-Jimal in his assessment of Nabatean influences on southern Syria (Glueck, 1951). In 1956, G. U. S. Corbett did exploratory

excavations of the Julianos church, from which he determined that Butler's founding date (fourth century) was erroneously based on a reused funerary text (Corbett, 1957). [*See the biographies of Horsfield and Glueck.*]

The Umm el-Jimal Project (1972–1995) excavated for eight field seasons over twenty-two years, under the direction of Bert de Vries, for Calvin College, Grand Rapids, Michigan. The first phase of the project consisted of five campaigns that ended in 1984. There is a current phase of excavation that is a series of summer field seasons. The project's overarching purpose has been to understand rural life on the Arabian desert frontier during the succession of Roman, Byzantine, and Early Islamic hegemonies. This began with the study of what was visible aboveground—the Late Antique town already described—but two major discoveries forced a backward expansion of historical horizons. The first was a fourth-century Roman fort *(castellum)* within the town's perimeter wall that was ruined and abandoned as the town grew around it. The second was a totally ruined village, about half the size of the town and 200 m to its east, dated to the heyday of Nabatean and Roman expansion in the Hauran (first–third centuries CE). [*See* Nabateans.]

The 1972–1973 season was devoted to mapping the site, to fill in details omitted from Butler's selective architectural survey. In 1974 preliminary soundings were dug as a representative sampling, which determined that the basic stratigraphic profile ranged from Late Roman to Umayyad. In 1977 the focus was on four major structures: the barrack, praetorium, house XVIII, and the perimeter wall. It was concluded that the town was continuously inhabited from the Late Roman through the Umayyad periods; no Early Nabatean Roman occupation levels were found. Fall 1977 was devoted to consolidating the barrack perimeter walls with force-pumped aerated cement.

In 1981 new work included the excavation of the northeast church, the Numerianos church, various water channels, and the Via Nova Traiana (6 km, or 4 mi., to the west). This work confirmed that the standing buildings are mainly the



UMM EL-JIMAL. *Plan showing relationship between the Late Antique town and the Nabatean-Roman village.* Areas labeled O, R, T, and W are 1984 excavation areas. (Drawing by Bert de Vries)

product of a rural agrarian culture that flourished in the Hauran from the fourth to eighth centuries CE. A major discovery was the identification of the ruined area (100 × 100 m) between the Roman reservoir and the east church as a *castellum* built in about 300 and used as part of the Roman frontier defenses in the fourth century. In January 1983, the gate of house XVIII was cleared and its walls consolidated.

In 1984 further work was done on the churches and the *castellum,* while the focus shifted to activities outside the walls of the Byzantine-Umayyad town. These included completing a walking survey of terrain within 10 km (6 mi.) of the town and excavating cemeteries and reservoirs east of it. The major discovery in that season was the Nabatean/Roman village (called al-Herri) buried under the rubble field adjacent to the reservoirs. The village began in the late first century CE, at the time of the last Nabatean expansion into southern Syria, flourished in the second and third centuries, and was destroyed during the turmoil of the late third century. The presence of this Nabatean/Roman site does much to explain the lack of earlier occupation layers under the Byzantine town. The numerous reused Nabatean and Greek inscribed tombstones must have been robbed from the cemeteries of this earlier village.

In 1992 architectural studies of four Late Roman and Early Byzantine structures (houses 35, 49, 119, and the praetorium) and detailed mapping of the *castellum* and the Nabatean/Roman village were carried out, including low-altitude aerial photography by Wilson and Ellie Myers. These survey data have been used to develop Geographic Information System (GIS) computer images and maps of the site. The 1993 season focused on consolidation and site development, including stabilizing the high walls of the praetorium and excavating house 119 in preparation for its adaptation as a museum and visitor center. House 119 proved to be a completely Umayyad construction on a cleared Byzantine domestic site. Field research in the 1994 season concentrated on the systematic excavation of the Nabatean-Roman village and studying the sixth-century burials outside the later town.

In summary, from the first to the third centuries CE, a small Arab village with both Nabatean and Roman features flourished at al-Herri. A praetorium and a few other imperial Roman structures were erected 200 m to the west. In about 300, the *castellum* was built; it lost its military function late in the fourth century. The much smaller barrack that replaced it was constructed early in the fifth century. As the imperial military presence diminished, the Early Byzantine town (fifth–sixth centuries), consisting of 129 houses and 15 churches, prospered, a product of a self-sufficient economy and political security. This town survived in somewhat diminished form through the Umayyad period. Following plague and earthquake in the mid-eighth century, the only human presence at the site for the next century was squatters in the ruins. Then, after centuries of inactivity, the town enjoyed a brief revival when Druze resettled it between 1910 and 1935.

BERT DE VRIES

UMM ER-RASAS, site located 30 km (18 mi.) southeast of Madaba in Jordan (31°30′ N, 35°55′ E; map reference 2374 × 1010). The extensive and well-preserved ruins consist of a rectangular fortified camp, or castrum (158 × 139 m). An open quarter of about the same size was found outside the castrum to the north.

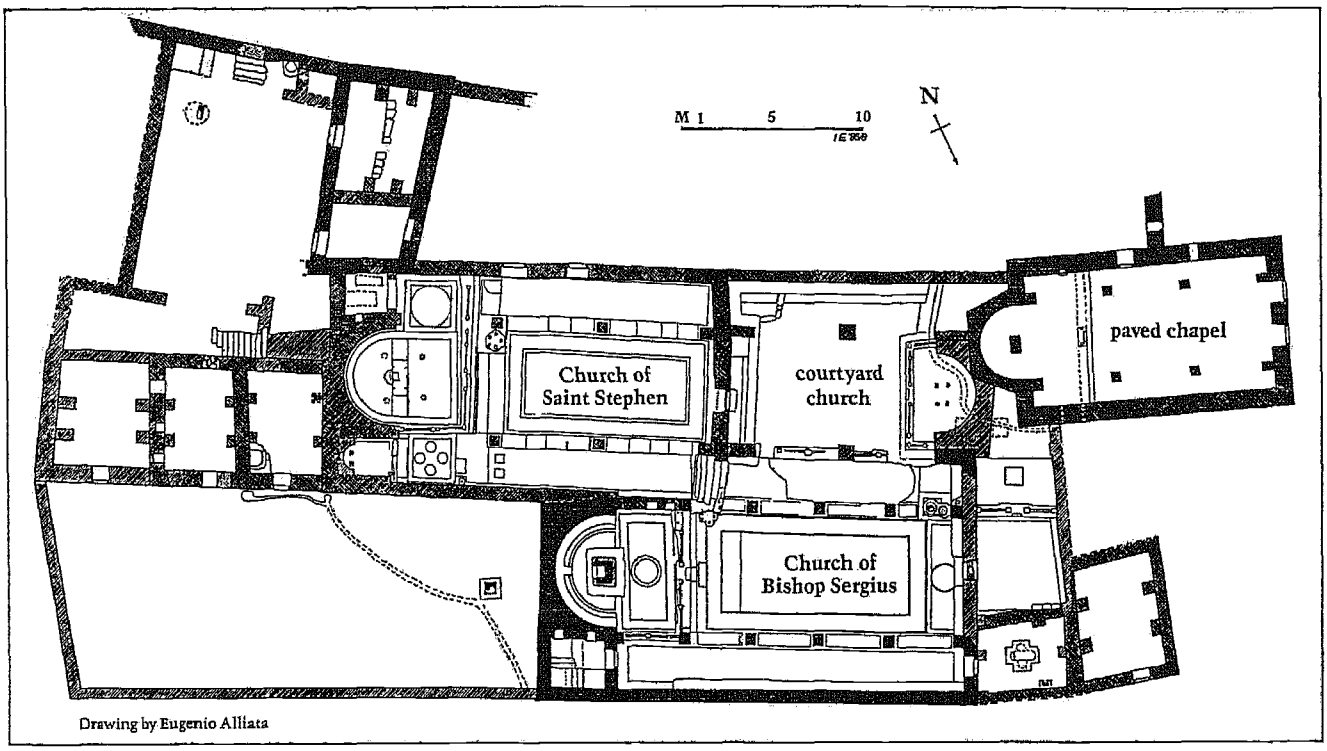
The ancient names of Umm er-Rasas were Mephaath/Mefaa/Kastron Meffaa/Mayfaʿa, as attested three times in the inscriptions in the mosaic floors of the site's excavated churches. Mephaath is listed as one of the places on the Moab plateau (*Jos.* 13:18, 21:37; *1 Chr.* 6:79, and *Jer.* 48:21). It was one of the Levitical towns that belonged to the tribe of Reuben. Eusebius, in his *Onomasticon* (128.21), and the *Notitia Dignitatum* list a Roman military camp in Mefaa. The biographies of the prophet Muhammad also record Mayfaʿa as the village whose inhabitants killed Zayd ibn ʿAmr, a pre-Islamic monotheist, on his way to Mecca to convert to Islam.

A team from the Franciscan Archaeological Institute in Jerusalem, led by Michele Piccirillo, has been conducting annual excavation seasons at the site since 1986, in collaboration with the Jordan Department of Antiquities. Their work has focused on a cluster of churches, rooms, and courtyards in an enclosed area in the northeast part of the site north of the castrum. They have named the cluster the St. Stephen complex, after the main church of the group (see figure 1).

The Church of St. Stephen, identified as such by its mosaic dedicatory inscription, is of exceptional importance. Its lovely nave mosaic depicts a number of cities in Transjordan and Palestine: Kastron Mefaa itself (including an enigmatic image of an isolated standing column), Amman, Madaba, Ḥesban, Maʿin, Rabba and Kerak in Transjordan; and Jerusalem, Nablus, Samaria/Sebaste, Caesarea, Lod, Beth-Guvrin, Ashkelon, and Gaza in Palestine. Representations of ten cities in the Egyptian Delta are also included as part of a Nilotic motif. The dedicatory inscription in the nave mosaic was damaged and repaired in antiquity; thus, the date as it now reads, 787 CE, is questionable and may be restorable as 718 CE. The apse mosaic has an intricate geometric design with a dedicatory inscription dated to 756 CE. These floors are among just a very few church mosaics in Jordan datable after the Muslim conquest. The many images of people and animals in the nave mosaic suffered deliberate damage that was carefully repaired. Limited probes below the eighth-century mosaics have revealed evidence of an earlier phase of the church.

Adjoining the Church of St. Stephen on the north is the Church of Bishop Sergius, which has a mosaic floor dedicated in 587 CE. The images in this mosaic floor suffered deliberate damage as well. To the west are a baptistery and funerary chapel. To the west of the Church of St. Stephen is a courtyard that was later converted into a chapel. To its west is the so-called Church of the Aedicula, with a flagstone pavement, the oldest church in the complex (sixth century CE). A series of rooms is to its south. Also part of the complex are rooms surrounding a courtyard to the east of the Church of St. Stephen and a courtyard serving as an atrium, along with another chapel to the south. Many burials have also been found throughout the complex.

The second area that has been under excavation by the Franciscans since 1989 is the Church of the Lions in the southeast part of the site, north of the castrum. It is a large



UMM ER-RASAS. Figure 1. *Plan of the St. Stephen complex.* (Courtesy ASOR Archives)

church surrounded by a series of rooms, forming a large ecclesiastical complex. Its mosaic is only partially preserved and does not have a surviving dedicatory inscription. The images in the mosaic floor were deliberately damaged. The mosaic also includes a second depiction of Kastron Mefaa with an isolated standing column. The church has an exceptionally well-preserved ambo (pulpit).

The church of the priest Wa'il, excavated in 1990 by Taysir Attiyat for the Department of Antiquities, is a small, single-apsed church in the northwest part of the site. It's mosaic floor is somewhat damaged. The inscription in the nave mosaic mentioning the priest Wa'il provides a dedication date of 586 CE for the church. The images were deliberately damaged.

Another prominent monument at the site is a well-preserved tower located about 1.3 km to the north of the castrum. It is 15 m high with a small, single-apsed basilica on its east side. This church, excavated by the Franciscans in 1987, and datable to the sixth century CE, has a plaster floor. Immediately to the north of the tower are large buildings, partially restored by the Department of Antiquities in the 1970s, near some covered water reservoirs.

Since 1988, the Mission Archéologique Suisse (Fondation Max van Berchem) under the direction of Jacques Bujard has been excavating inside the castrum in a complex of two side-by-side churches in the southeast corner. The construction of the two churches postdates the construction of the castrum wall. The north church is the earlier of the two. It is a single-apsed basilica with a heavily damaged mosaic floor belonging to a second phase. The images were deliberately damaged. An inscription provides a dedication date of either 578–579 or 593–594 for the mosaic. The south church is also a single-apsed basilica. Its mosaic floor is very badly damaged, and no dedicatory inscription is preserved. The Swiss team has also cleared portions of the large courtyard to the south of the two churches and a portion of the exterior face of the east castrum wall.

The town as a whole appears to have been largely abandoned by the late eighth or early ninth century. Because excavation has focused on the churches from the Byzantine and early Islamic periods, the nature of any Iron Age or Nabatean settlement remains unexplored. Iron Age sherds were found in one deep sounding in the St. Stephen complex, however.

[*See also* Churches; Mosaics.]

BIBLIOGRAPHY

Brief notices of the Franciscan excavations have been prepared each year since 1986 by Michele Piccirillo and published in *Liber Annuus.* Several lengthier articles in Italian have appeared in the same journal. Those about the Church of Saint Stephen have been superseded by the final report (Piccirillo and Alliata, 1994), but for the other excavation areas, they remain fundamental.

ROBERT SCHICK

UMM QEIS (ancient Gadara), site located on the northern Transjordanian tableland east of the Jordan Rift Valley (32°37′ N, 35°41′ E). The layout and size of the ancient city were apparently adapted to the topography of a flat limestone plateau that drops steeply on the north, south, and west from an altitude of 364 m above sea level. This plateau commands a panoramic view across the great plain of the Jordan Valley, the Lake of Tiberias (biblical Lake Gennesar), the Yarmuk Valley, the Golan Heights, and Mt. Hermon.

The identification of Gadara with the site of the ruins of present-day Umm Qeis was determined by Ulrich J. Seetzen as early as 1806 (*Reisen durch Syrien*, ed. Friedrich Kruse et al., vol. 1, Stuttgart, 1854, p. 368) and has long been regarded as settled. The main evidence is provided by the hot springs at el-Ḥamma (Emmatha) in the Yarmuk Valley, for which nearby Gadara (situated 553 m above el-Ḥamma) was famous, that are still found there. First mentioned by the first-century BCE Roman geographer Strabo (16.2.29), they have been praised ever since for their medicinal qualities.

According to Siegfried Mittmann (*Beiträge zur Siedlungs- und Territorialgeschichte des Nördlichen Ostjordanlandes*, Wiesbaden, 1970, p. 130) Gadara lay 16 Roman miles from both Capitolias/Beit Ras and Scythopolis/Beth-Shean; Roman milestones remain from both roads, as well as from that leading from Gadara to Tiberias. The springs, also named Termae Haelia are at the third milestone on the road between Capitolias and Tiberias.

Claudius Ptolemaeus (*Geographia* 14.22), a second-century CE Roman writer, includes Gadara on his list of eighteen cities belonging to Coele-Syria and the Decapolis. Pliny the Elder (*Nat. Hist.* 18.74) noted that historians differed in listing the Decapolis cities; his own list of ten, which included Gadara, dates to the first century CE. [*See* Decapolis.]

Of the cities of the Decapolis, Gadara is most renowned as the birthplace of illustrious men, among them Philodemus the Epicurian, a contemporary of Cicero, and the great poet Meleager.

Gadara was first visited by Seetzen in 1806 and surveyed by Gottlieb Schumacher in 1886. This was followed by sporadic fieldwork that recovered a Late Antique bath in the northwest section of the site with a mosaic floor and a mosaic inscription (1959), a subterranean mausoleum (1968), and a Late Roman tomb (1969), which was cleaned. [*See the biography of Schumacher.*]

Since 1974, the German Evangelical Institute for the Archeology of the Holy Land has undertaken systematic survey, excavation, and restoration work at Umm Qeis. [*See* Deutsches Evangelisches Institut für Altertumswissenshaft des Heiligen Landes.] A 1974 survey yielded evidence for an occupation at least as early as the seventh century BCE. However, in considering the history of Umm Qeis/Gadara, it is the literary tradition that is relied on primarily Polybius (*Hist.* 5.54–85) described the region of Gadara as one of several locations under Ptolemaic control before the conquest of Antiochus III in 218–217 BCE. During the final conquest of Transjordan and Palestine by this Antiochus in 198 BCE, Gadara was incorporated into the Seleucid kingdom—an important event in the city's history. According to Stephan of Byzantium (*Ethnika* 128.30), the city was called Antiochia and Seleucia, and it minted coins bearing the title "Antiochia" to commemorate the heritage of Seleucid control. [*See* Seleucids.]

Josephus, the first-century CE Roman historian (*Antiq.* 13.13.3; *Wars* 1.4.2), mentions that Gadara was freed from the control of the Hasmonean king Alexander Jannaeus by the Roman general Pompey during Pompey's campaign in Syria in 63 BCE. It was part of the reorganization that resulted from the formation of the Provincia Arabia after the Romans annexed the Nabatean kingdom and its capital city, Petra, early in the second century CE. [*See* Nabateans.] Additional reorganization took place in the Roman Empire with the creation of the Provincia Palaestinae. By about 429 CE, Palestine and Transjordan were subdivided into Palaestina Prima, Palaestina Secunda, and Palaestina Tertia. George Adam Smith has pointed out (*Historical Geography of the Holy Land*, 25th ed., rev. London, 1931) that Gadara was listed as one of the cities in Palaestina Secunda.

During the New Testament era, a visit by Jesus to the region of Gadara is attested (*Mt.* 8:28). The city is best re-

membered in connection with the story of the Gadarene swine. By the beginning of the fourth century CE, Gadara had a bishop who attended the Council of Nicaea (325 CE). As a result of the discovery of its magnificent basilica by the German Evangelical Institute for the Archaeology of the Holy Land under the direction of Ute Wagner-Lux (1976–1980), Gadara is among the major Christian centers in Transjordan, which include Jerash/Gerasa, Madaba, and Petra. [*See* Jerash; Madaba; Petra.] The remains of other monuments in the city include two temples, two theaters, a fortified acropolis, paved colonnaded streets, a monumental gateway, a necropolis, a nymphaeum, two mausolea, a stadium, and two public baths along the south side of the *decumanus maximus*.

The excavation of the bath building in 1977–1983 by a Danish team headed by Svend Holm-Nielsen discerned three main periods in its history. The first was terminated by a destruction possibly caused by an earthquake in about 400 CE. In the second, the building continued as a bath but on a much reduced scale, the gradual change indicating an economic decline at Gadara. At some time in the first half of the seventh century, the use of the building as a bath came to an end. In the third period of its history, the bath was used for habitation and workshops. A section of the building seems to have been used as an Islamic prayer place in the Umayyad period. Al-Baladhuri, a ninth-century Arab historian says (*Kitab futuh al-buldan* [Book of the Conquest of the Countries], ed. M. J. de Goeje, Leiden, 1866, p. 126) that in the middle of the seventh century Gadara was captured by the Muslims and became one of the cities of the new Arab administrative district of Falastin (Palestine).

UMM QEIS. *Ruins of the central portion of the basilica.* (Courtesy A. Hadidi)

Little is known of Gadara's history in ʿAbbasid and later periods. Neither Christian nor Muslim writers provide any indication of whether Gadara was settled during the Ayyubid-Mamluk period. The frequency and distribution of sherds from this period (eleventh–thirteenth centuries CE) at Gadara probably reflect the existence of a few farms in the immediate vicinity. Accounts of Arab travelers and geographers indicate that there was a sharp decline in the city's wealth and population and that gradually Gadara passed from a Greco-Roman town of considerable importance, even boasting a university in its heyday, to a field of ruins.

UNDERSEA EXPLORATION SOCIETY OF ISRAEL.

In 1959, hundreds of amphorae were hauled up from the sea bottom by trawler fishermen from Kibbutz Maʿagan Mikhaʾel. The investigation of that rich collection of archaeological finds was the impetus for the establishment of the Undersea Exploration Society of Israel (UESI). The following year, the American explorer and diver Edwin Link arrived in Israel to explore the Herodian harbor at Caesarea, providing the Israeli group of navy-trained divers and the kibbutz's Elisha Linder, who had traced the provenance of the amphorae on the sea floor, with an opportunity to participate in an underwater excavation. Soon after, pioneer American archaeological diver Peter Throckmorton was invited to serve as guide and mentor in conducting underwater surveys for the growing number of enthusiastic UESI vol-

unteers. This component of learning by experience extended to include the application of advanced technology for searching and surveying the sea floor, like the sonar developed by H. Edgerton.

Members of the UESI have participated in marine archaeological excavations elsewhere in the Mediterranean region as well: at the Yassıada wreck in Turkey; at Kyrenia in Cyprus; and in the Straits of Messina and the Lake of Bolsena in Italy, among them. The knowledge obtained while training abroad and diving at home raised the society's professional standards and its reputation among archaeologists.

During UESI's first decade, its members participated in the major harbor excavations at Akko, ʿAtlit, and Caesarea. Its local branches at various coastal settlements, while monitoring assigned stretches of the coastline, were recording and rescuing important finds, such as the Shavei-Zion Tannit figurine wreck. [*See* Shavei-Zion, *article on* Underwater Site.] The UESI also works in the Sea of Galilee and the Red Sea. The society was instrumental in the creation of the National Divers Federation and participates with oceanographers in interdisciplinary maritime study projects. In 1972, Elisha Linder, joined later by Avner Raban and Yaʿacov Nir of the UESI, initiated a program of graduate study at the University of Haifa in the history of maritime civilizations. Although, gradually, volunteer divers have given way to professionally trained marine archaeologists on excavations, the divers on many expeditions continue to be drawn from UESI's rank and file.

UNDERWATER ARCHAEOLOGY. The field of underwater archaeology offers unique information about the past because artifacts found under water are often better preserved, and in larger quantities, than those found on land, where in the past ceramics and glass eventually were broken through use, metal objects were melted down and recast, and raw materials were transformed into manufactured goods after they were unloaded from the ships that transported them. Organic material often simply disappears. Furthermore, if artifacts are from a shipwreck that can be dated precisely, as is often the case, they can be equally well dated, contributing to the establishment of precise chronologies.

The archaeology of ships, sometimes called nautical archaeology, also reveals design and construction details of various types of watercraft—of merchant vessels, such as those found at Serçe Limanı, Uluburun, and Yassıada in Turkey; warships, a ram at ʿAtlit in Israel; and fishing boats, such as the Galilee Boat recovered from the Sea of Galilee. Underwater archaeology, however, also embraces the study of ancient harbors, as at Caesarea in Israel, and inundated settlements, such as several Neolithic sites in the sea south of the port of Haifa. [*All of the sites mentioned above are the subject of independent entries.*]

Underwater archaeology in the Near East began, as elsewhere, with chance finds made by fishermen, sponge divers, and, after the invention of self-contained underwater breathing apparatus (SCUBA), both sport and scientific divers. Ancient wrecks have been reported off the coasts of every country washed by the Mediterranean or Red Seas.

It was a discovery by sponge divers near Cape Gelidonya, Turkey, that led in 1960 to the first complete excavation on the floor of the Mediterranean. The approach to that excavation was to adapt, as much as was practical, standard land techniques to the underwater environment. The site was mapped by triangulation with meter tapes (details were added to plans from pencil drawings made under water on plastic paper) and from site photographs taken with cameras in watertight housings. Instead of shovels and wheelbarrows, excavators used air lifts, or nearly vertical suction pipes, to remove overburden. Because sunken objects often become encased in layers of calcium carbonate over time, it was necessary to chisel free from the seabed large clusters of solidly concreted artifacts. These were raised with balloons filled with air after being attached to the clusters and were then dismantled on land. [*See* Cape Gelidonya.]

The Cape Gelidonya excavators learned that the major problem in working under water is lack of time, for in order to avoid decompression sickness, each excavator could work for only about an hour a day in two dives. Thus, in the 1960s, the excavation of Late Roman and Byzantine shipwrecks at Yassıada, Turkey, led to the development of devices to improve efficiency, especially in mapping. These included metal grids placed over a site to break it into squares 2 meters on a side; a scaffolding to support movable photographic towers; underwater plane tables; and ultimately a system of mapping stereophotogrammetrically by moving a camera along a horizontal bar floated over the site. Later, the stereophotographs were taken from a research submersible that glided above the seabed as an airplane flies over land. An air-filled Plexiglas hemisphere on legs (called an underwater telephone booth) allowed divers to talk to one another or, via a cable, to the surface; and a submersible decompression chamber allowed excavators to make longer dives by decompressing longer. It was also in the 1960s that the first ancient wreck was located by side-scan sonar, near Yalıkavak, Turkey.

In the late 1970s, at Serçe Limanı, ceramic containers were sieved for seeds and other organic remains for the first time, with excellent results, and excavators gained more diving time by decompressing on pure oxygen. By the 1980s, the new techniques for underwater mapping were abandoned at Uluburun, because of the rugged seabed terrain, and mapping was again done with hand-held meter tapes and plumb bobs, although a newly invented acoustic mapping system (SHARPS) was also used.

Except for limitations on time, the major difference between underwater archaeology and land archaeology has to do with conservation. When an iron artifact falls into the sea, for example, it can be completely covered by calcium carbonate within a year. This thickens over the ages as the iron disintegrates through corrosion, leaving a perfect mold inside. Hundreds of amorphous lumps of concretion are plotted on wreck plans and are then X-rayed to see the outlines of what once was inside. The natural molds of concretion are next broken into pieces, the slight remains of rust are removed, and the cavities are filled with epoxy. Once the epoxy hardens, the concretion is removed with pneumatic chisels, leaving exact replicas of the original implements.

Waterlogged wood will quickly shrink and warp out of recognition in air as its cells collapse, unless it is bulked with something before the water in them evaporates. Excavators of the fourth-century BCE Greek shipwreck near Kyrenia, Cyprus, using polyethylene glycol, were the first to conserve the fragmentary timbers of a Mediterranean ship, which they reassembled in the early 1970s from thousands of fragments of wood held together with stainless steel wire. This process was repeated in the 1980s and 1990s on the eleventh-century Serçe Limanı ship.

UNITED ARAB EMIRATES. In 1971, the former Trucial States of Abu Dhabi, Dubai, Sharjah, Ajman, Umm al-Qaiwain, and Fujairah formed a federation called the United Arab Emirates (UAE). In this they were soon joined by the northernmost emirate. In the Oman peninsula, Ras al-Khaimah. Archaeological exploration in the former Trucial States began in the late 1950s with a Danish expedition from the University of Aarhus (1959–1965) working on a series of large collective burials and on an associated settlement from the mid- to late third millennium BCE on Umm an-Nar island in Abu Dhabi. In 1968, Karen Frifelt took up the expedition's work in the Hili district of the Buraimi oasis and Beatrice de Cardi undertook the first of several surveys in Ras al-Khaimah. In 1973–1974 an Iraqi team worked at a number of important sites, and a series of French missions under Serge Cleuziou and Rémy Boucharlat was inaugurated in 1977 to investigate Hili 8, Rumeilah, and Mleiha. Meanwhile, numerous other foreign teams began projects in the mid- and late 1980s at sites ranging from prehistoric shell middens to the medieval port of Julfar. Many of these are still underway.

The UAE occupies an important area at the base of the Arabian Gulf and consists of four environmental zones. The flat, sandy desert foreland on the coast, which extends from the bottom of the Qatar to the beginning of Ras Musandam, is backed by a strip of fertile, well-watered gravel plains. To the east and north of these rises the massive Hajar mountain range, which runs like a backbone down the center of the Oman peninsula. To the south, the desert begins, punctuated only occasionally by oases like Liwa, and gradually merges into the great Rub al-Khali sand sea. The so-called east coast of the UAE is that portion of Ras al-Khaimah, Sharjah, and Fujairah that represents a continuation of the Batinah coastal plain of Oman and fronts the Arabian Sea. There, a series of historically important harbors, such as Dibba, Khor Fakkan, Fujairah, and Kalba, look eastward toward the Indian subcontinent; traditionally, the Gulf ports of Abu Dhabi, Dubai, Sharjah, Ajman, Umm al-Qaiwain, and Ras al-Khaimah have been more oriented culturally toward Iran, Bahrain, and Iraq.

Sites belonging to the late prehistoric Arabian bifacial lithics tradition (c. 4500–2800 BCE) are found at many points along the Gulf coast of the UAE, from Abu Dhabi in the south to Ras al-Khaimah in the north, and inland around Khatt and Jabal Hafit. The coastal sites exploited the rich marine resources available, particularly shellfish, and probably represent seasonal encampments of pastoralists who spent the winter in the interior with their herds and their summers on the coast. By about 3100 BCE, a large sedentary settlement with mud-brick architecture had been established at Hili 8, in the Abu Dhabi part of the Buraimi oasis. A full range of domesticated cereals, including emmer; bread wheat; two-row, six-row hulled, and six-row naked barley; and sorghum (?), as well as dates and melons, were being grown there, and domesticated sheep, goat, and cattle were kept. Wild camel and equids were also being hunted. The site is contemporary with a series of stone burial cairns of the so-called Hafit type containing individual inhumations. The burials have yielded imported Mesopotamian ceramics and beads of the Jemdet Nasr and Early Dynastic type. By the middle of the third millennium BCE, a distinctive culture complex known as Umm an-Nar (c. 2700–2000 BCE) had emerged, characterized by well-made black-on-red/orange painted pottery (see figure 1); soft-stone vessels decorated with a simple dotted double circle; large circular communal graves faced with well-cut ashlar masonry; and large circular fortifications built of mud brick and/or stone (about 20–40

UNITED ARAB EMIRATES. Figure 1. *Ceramics from a late Umm an-Nar tomb.* At Tell Abraq, c. 2100–2000 BCE. (Courtesy D. T. Potts)

m in diameter). Historically, this culture, which was in touch with the Indus Valley, eastern Iran, and Mesopotamia, probably represents the land known in cuneiform sources as Sumerian Magan (Akk., Makkan). Copper mining and refining was a major industry in the interior, where substantial areas of Bronze Age slag have been identified (e.g., near Maysar in the Wadi Samad).

During the Wadi Suq period (c. 2000–1200 BCE) fewer settlements seem to have existed, perhaps as a result of slightly more arid conditions. Tell Abraq, however, was occupied continuously from the Umm an-Nar period through the Iron Age, demonstrating that the abandonment of sites was not a universal phenomenon. At Shimal, in Ras al-Khaimah; Qidfa, in Fujairah; and Qaṭṭarah, in al-ʿAin, large graves constructed of local stone have been found (c. 2000–1700 BCE) containing the characteristic fineware beakers and spouted jars of this period, as well as an impressive amount of bronze weaponry (e.g., swords and socketed spearheads). Contact with Bahrain in the early second millennium BCE is indicated by a sizable amount of Barbar red-ridged pottery at Tell Abraq; later contacts with Mesopotamian and Elam are suggested by Kassite and Middle Elamite ceramics. The camel was probably domesticated by about 1500 BCE, according to the latest evidence from Tell Abraq.

The Iron Age (c. 1200–300 BCE) can be divided into at least three distinct phases, based on the evolution of the ceramic assemblage. This was a period of expanded settlement throughout the region, possibly as a result of the introduction of a new form of irrigation in which groundwater was tapped via subterranean surface channels (Pers., *qanat;* Ar., *falag* [sg.], *aflag* [pl.]). Key settlements include Tell Abraq, Rumeilah, and Rafaq. There are few Hellenistic period sites, but an important settlement existed at Mleiha in the interior of Sharjah, where monumental graves; workshop areas for bone, stone, and metal; domestic houses; and part of a square fortress with square corner towers have been excavated. Mleiha was also the site of a mint. The first century CE is best represented at ed-Dur, on the coast of Umm al-Qaiwain. Imported goods such as terra sigillata, Indian red polished ware, glazed Parthian pottery, Roman glass, southeast Iranian black-on-red Namord pottery, Mesopotamian eggshell ware, and Characene coins attest to the site's cos-

mopolitan nature. A third–fourth-century CE phase is also represented in area F at ed-Dur, where examples of early Sasanian glass have been found in a group of burnt offerings and shallow inhumations. A Late Sasanian/Early Islamic horizon is known at Jumeirah, in Dubai, where several large buildings, possibly a caravanserai and market, have been found. The most important medieval site investigated to date is the port of Julfar, on the coast of Ras al-Khaimah, where the abundance of Far Eastern ceramics and coins attests to the far-flung nature of the site's international trade during the fourteenth–early sixteenth centuries CE. The Portuguese are also known to have built a fort there during their brief period of supremacy in the region.

UPPER EGYPT. The southern portion of Egypt, known as Upper Egypt, was divided into twenty-two nomes based upon the Karnak list from the reign of the twelfth-dynasty king Senwosret (Sesostris) I (1971–1926 BCE). The traditional southern border was Aswan at the First Cataract of the Nile. The northern border was between Lisht and Dahshur just north of the entrance to the Faiyum. The narrow ribbon of the Nile Valley within Egypt lies in Upper Egypt. The territory included in Upper Egypt can be divided into three parts: southern Upper Egypt, from Aswan to Thebes; northern Upper Egypt, from Nag el-Medamud to Qaw el-Kebir; and Middle Egypt, from Asyut to Lisht.

The textual and archaeological records from Upper Egypt are much more extensive than from Lower Egypt. The record is biased by the fact that modern excavation focused more on the monumental art and architecture of the south, and because of better preservation on the dry margins of the upper Nile Valley than in the low lying and wetter Nile Delta.

The Upper Egyptian sequence of predynastic cultures begins in the fourth millennium BCE. The earliest is the Badarian followed by the Naqada I and II periods (consisting of the Amratian and Gerzean cultures) that was to develop into the dominant "great tradition" of early pharaonic civilization, and to overtake the Delta to effect a unified kingdom.

Already at the end of the Amratian period (Naqada I) the site of Hierakonpolis, ancient Nekhen, modern Kom el-Ahmar, was developing into a major urban center with specialized ceramic and beer production known from the archaeological record. By late Gerzean and Protodynastic (Naqada III) times, Hierakonpolis was one of several possible "mini-states" in the area of the Qena bend, where the course of the Nile swings east toward the Red Sea and then back westward. Hierakonpolis, situated just below the bend, must have been a virtual late Predynastic capital; other important settlements of the time include Coptos and Naqada, near the entrance of the Wadi Hammamat connecting the valley to the Red Sea coast. According to later tradition, the kings of the first dynasty hailed from This, capital of the eighth nome (province), just north of the Qena bend. The first-dynasty royal tombs are found at Abydos on the desert edge to the southwest of This. Abydos became the cult center of Osiris at the end of the Old Kingdom (c. 2150).

These centers became somewhat provincialized with the great move to the north during the third and fourth dynasties in the early Old Kingdom (c. 2650–2465). The pyramid clusters of Abu Roash, Giza, Abu Sir, Saqqara, and Dahshur all properly belong to Memphis, the new capital, situated in the first nome of Lower Egypt. Toward the end of the Old Kingdom, the Upper Egyptian provinces reasserted themselves as important centers in their own right with major cemeteries containing the tombs of local administrators at sites like Gebelein, Deir el-Gabrawi, Meir, and Deshasha. At Aswan are the tombs of sixth-dynasty nomarchs (provincial governors) and caravan leaders whose tomb biographies—a genre just developing at this time—inform us about the political situation between Egypt and Nubia toward the end of the Old Kingdom. About the same time, the tomb of Inti at Deshasha appears to portray the Old Kingdom seige of a fortified center in Palestine.

When the Old Kingdom collapsed shortly after the reign of Pepi II, penultimate ruler of the sixth-dynasty, Upper Egypt broke up into its constituent nomes. There is evidence

of extremely low Nile flood levels and famine in Upper Egypt during the ensuing First Intermediate Period (seventh–mid-eleventh dynasties, c. 2150–2040). As large polities coalesced toward the end of this period, those in Upper Egypt formed again in the area of the Qena bend under the control of the Intefs from Thebes, modern Luxor. The center of power in the north was the first nome of Lower Egypt ruled by the dynasty of obscure rulers, some of whom were named Khety, at Herakleopolis, modern Ihnasya el-Medina. The tombs at Asyut from this period tell us in very fragmentary texts about the armed conflict between the two powers.

The southerners were once again victorious and the Middle Kingdom (late eleventh–twelfth dynasties, c. 2040–1780) was inaugurated by a descendant of the Intefs, Nebhepetre Mentuhotep, who built the great terraced temple at Deir el-Bahari that Hatshepsut copied and superseded generations later. The founder of the twelfth dynasty, Amenemhat I, moved back to the north and established his capital of Itj-tawy ("seizing the two lands") near Lisht where he revived pyramid-building. The succeeding kings of the twelfth dynasty built their pyramids at Lisht (Senwosret I), Dahshur (Amenemhat II, Amenemhat III, Senwosret III) and near the Hawara channel that gives access from the Nile valley to the Faiyum (another by Amenemhat III, Senwosret II).

Kings Senwosret I and III built a string of great mud-brick fortifications in lower Nubia, particularly around the Second Cataract where the Semna and Kumma forts became checkpoints for Nubian trade passing northward. The forts signify Egypt's concern with its southern border, probably because of the Kerma culture growing toward statehood below the Third Cataract. The twelfth-dynasty rulers were also concerned with the northeast, more for commerce than coercion, although some texts give evidence of a campaign of Amenemhat II in Palestine (Nicholas Grimal, *A History of Ancient Egypt,* Cambridge, 1992). Egypt's fears were apparently well founded, for when the Egyptian kingdom began to disintegrate in the thirteenth dynasty (after c. 1780), the strong secondary state of the Hyksos filled the power vacuum in the northeast Delta, and the Nubian Nile Valley came under the domination of the Kerma rulers.

When the Egyptian kingdom reasserted itself by attacking and defeating the kingdoms of Kerma and of the Hyksos, it was, once again, from the area of the Qena bend under seventeenth-dynasty kings. The final expulsion of the Hyksos under Ahmose (c. 1550–1525) initiated the eighteenth dynasty. Thebes and Upper Egypt experienced a golden age. Pyramids were abandoned for royal tombs to be replaced by rock-cut corridor tombs in the Valley of the Kings (see below). Thebes became a southern capital in counterpart to a revived Memphis in the north. The east bank was given over to settlement, probably palaces and temples of the state god, Amun-Re, his consort, Mut, and their child, Khonsu. The west bank became a vast necropolis, both royal and private, with the tombs of the nobles scattered across the el-Qurna hill, the Valley of the Queens to the south, and the Valley of the Kings to the north. The eastern base of the pyramidal hill that towered above these communal cemeteries supported a string of mortuary temples that grew during the course of the eighteenth through the twentieth dynasties (1550–1070).

For more than four hundred years the west bank of Waset (ancient Luxor), known as the Valley of the Kings, was the burial ground for royalty and all important government officials. The chapels of private individuals continued to be decorated with lively scenes of everyday life. The kings' tombs, however, bore scenes of the magical-religious texts known as the *Book of the Dead,* the *Book of Gates,* and the *Book of What is in the Underworld.* In these texts, the deceased kings joined the sun-god in his nightly journey through the underworld to be reborn with him in the morning on the eastern horizon. Funerary temples were built on the west bank. On the east bank, the importance of the royal cult was being eroded by that of the state gods, especially that of Amun-Re at Karnak. All the great temples such as the temple at Luxor were decorated with sculpted and painted relief scenes on all available space.

Recently the tomb of the sons of Rameses II was rediscovered in the Valley of the Kings. It was used for the burial of fifty-two sons of the king and may also have a second level. It is the largest tomb in the valley.

The construction of the tomb changed during this time. The simple oval or rectangular graves of the predynastic period were expanded to include a building above the ground with a superstructure consisting of a flat roof and vertical mud-brick walls. At the beginning of the Old Kingdom the kings built their tombs as pyramids. There are about ninety-seven pyramids dated from the third dynasty until the end of the Middle Kingdom. Every pyramid complex consisted of the pyramid, a surrounding courtyard and enclosure wall, a temple at the pyramid's eastern base, a causeway to the valley floor, and a valley temple.

The influence of Thebes and Upper Egypt diminished toward the end of the New Kingdom in favor of cities in the Delta that had been established already in the eighteenth dynasty. Kingship was weakened in the south by the growing power of the priesthood of Amun, until Upper Egypt came to be under its administration, and twenty-first-dynasty pharaohs ruled from the north. The sequence of royal burials in the Valley of the Kings came to an end. Thebes and Upper Egypt were never to regain the dominant position they held in the New Kingdom as Egyptian power became increasingly concerned with international relations to the northeast and northwest. The Delta grew in importance as Egypt faced and was subjugated by the empires of Assyrians, Persians, Macedonians, and Romans.

ZAHI HAWASS

UR (Ar., Tell el-Muqayyar), site located in southern Mesopotamia (modern Iraq) along a former branch of the Euphrates River (30°56′ N, 46°08′ E). The site was identified as Ur in the 1850s by the British consul at Basra, J. E. Taylor, who was employed by the British Museum to investigate a number of southern Mesopotamian sites, about which almost nothing was known at the time. He dug at the corners of the ziggurat mound at the site, uncovering a number of baked clay cylinders inscribed in cuneiform. The inscriptions detail the history of the building of the ziggurat and named the city as Ur, which for many people implied an identification with the biblical city of Ur of the Chaldees, the birthplace of Abraham (*Gn.* 11:28–31).

Following Taylor's work, the site was left untouched until nearly the end of the century, when a team from the University of Pennsylvania excavated there briefly. Immediately following World War I, R. Campbell Thompson and H. R. Hall tried their luck. It is C. Leonard Woolley, however, director of twelve field seasons at the site (1922–1934), who is credited with most of the archaeological work at Ur.

The Woolley expedition was jointly sponsored by the University Museum of the University of Pennsylvania and the British Museum. It was a model for its time in terms of the quality of much of the fieldwork and the timeliness and thoroughness with which the work was published. Woolley's engaging and prolific popular prose, his flair for publicity, the spectacular nature of some of his finds, and the connections he drew between Ur and the Bible all combined to produce strong public interest in his work, rivaling that elicited by King Tutankhamun's tomb in Egypt. Since 1934, work at the site has been limited to that associated with the restoration of the ziggurat by Iraqi archaeologists.

Ur was occupied for approximately four thousand years, from the Ubaid (fifth millennium) to the Neo-Babylonian (mid-first millennium BCE) periods. However, as is invariably the case on large, deeply stratified Near Eastern mounds, the earlier phases of occupation have been far less extensively investigated because of their inaccessibility. Ur's long history has also played a role in limiting access to its past. The city reached its zenith in the Ur III period (c. 2100–2000 BCE), when it was the capital of an empire and its kings undertook extensive building programs, obscuring earlier structures. Woolley's predilection for excavating in the so-called Temenos area of the site—the location, since very early in Ur's history, of major temples and other elaborate buildings—also contributes to a picture of life at Ur that is heavily, albeit not exclusively, centered around the community's religious and civic core.

To explore the early occupations of Ur, Woolley instructed his workmen to sink several deep test pits. Under the fourth-millennium occupational layers (see below) they encountered a thick, culturally sterile layer thought to have been deposited by the action of water. This was quickly dubbed the "Flood Stratum" and interpreted as the remnants of the biblical flood. In fact, the deposit may be a wind-borne dune or, if water-borne, a product of just one of many floods that were common occurrences in Mesopotamia prior to modern damming of the rivers.

Below the sterile "Flood" deposit were the remains of Ubaid occupation. Ur may have reached a size of 10 ha (25 acres) in the Ubaid period, making it one of a number of larger towns amid a landscape of predominantly small villages. However, the remains that Woolley excavated reveal a picture of ordinary domestic life. No intact architecture was recognized, but bits of mud brick and remnants of reed-and-mud constructions were recovered, mixed with domestic debris including pottery with simple painted designs; stone tools for a variety of cutting, pounding, and grinding tasks; sickles made of highly fired clay; and spindle whorls.

In addition to the domestic remains, the excavations encountered a small number of Ubaid graves. Individuals were interred on their back, accompanied by a few pots, occasionally clay figurines, and more rarely beads or animal bones. There are few differences in the ways these individuals were treated at death, apart from distinctions attributable to age and sex.

The scanty excavated remains from the Uruk and Jemdet Nasr periods (c. 3900–2900 BCE) are nevertheless sufficient to suggest that Ur remained a town of some importance. Excavations around the later ziggurat revealed an Uruk-period temple platform, consisting of a terrace wall built of characteristically Uruk *Riemchen* bricks (square in cross section) and a floor strewn with thousands of the clay cones favored for decorating the facades of public buildings of this period. Elsewhere on the site pottery kilns accompanied by masses of pottery were uncovered. A portion of an extensive cemetery was also excavated. Woolley attributed the graves

to the Jemdet Nasr period, but recent reevaluations assign them to the Uruk through Early Dynastic II periods. Bodies lay on their side in a crouched position, frequently accompanied by clay pots, stone vessels, and beads, and less often by metal (copper or lead) vessels or other small copper items.

In the succeeding Early Dynastic period (c. 2900–2350 BCE), the temple platform, already prominent in the Uruk and Jemdet Nasr periods, was rebuilt at least twice. Kitchens, storerooms, and a series of rooms interpreted by Woolley as shrines were found on top of it. The temple that was presumably the principal building on this platform is not directly attested, having been buried beneath the massive ziggurat built by the Ur III king Ur-Nammu.

Not far from the temple platform was a rubbish dump, known as the seal-impression strata (SIS). The dump included burnt mud-brick debris, pottery, clay tablets, and the many clay sealings from which the strata take their name. Based on its location as well as its contents, the rubbish probably derives from temple or civic buildings of the Early Dynastic period. The seal impressions include those known as the city seal impressions because of their protocuneiform symbols, which are thought to stand for city names. The sealings had been used to close doors, presumably of storerooms, as well as jars and other containers. The relative frequency with which certain city names co-occur may relate to the strength of economic connections between cities.

Dug into this rubbish dump were the graves of the Royal Cemetery. The cemetery was used as a burial place from the Early Dynastic III through the Post-Akkadian periods (c. 2600–2100 BCE) and contained approximately two thousand graves (although many badly disturbed ones were unreported). The cemetery derives its name from sixteen of the graves, all of which date to the earliest portion of its use. Unlike the hundreds of other graves, these sixteen, known as the Royal Tombs, contained brick and/or stone chambers in which the dead were placed. All of the tombs contained multiple burials of individuals apparently placed in the grave to accompany the principal deceased person ("human sacrifice"). Where subsequent disturbance did not remove the evidence, the tombs included great riches of precious metal and semiprecious stone jewelry, containers, weaponry, musical instruments, seals, and furniture. However, as Woolley himself pointed out, a number of the so-called private graves also contained similar types and quantities of riches. What best distinguished the "royal" tombs were their construction and seeming evidence of human sacrifice.

On the basis of the treatment of the deceased and the discovery in several of the tombs of inscribed artifacts naming a person as "king" or "queen," Woolley argued that these were the tombs of royalty. However, none of the inscribed artifacts were found directly associated with the principal deceased individual, and they may have been gifts from others, rather than possessions of the dead person. Although it cannot be stated with certainty who was buried in the Royal Cemetery graves, a consideration of the full range of interments and comparison with burial practices at contemporary sites suggest that the Royal Cemetery includes personnel from both religious and civic institutions.

Apart from the continuing use of the Royal Cemetery for burial, there is little direct evidence of the Akkadian period at Ur, although contemporary texts indicate that it remained an important city. An alabaster disk showing a ritual act of libation has an inscribed dedication from Enheduanna, who was a daughter of Sargon, the founder of the Akkadian dynasty. Enheduanna served as *en*-priestess (high priestess) of Nanna, the patron god of Ur. Enheduanna's installation in the post of *en*-priestess at Ur may represent one means by which Sargon sought to cloak his rule of the many city-states of Sumer and Akkad in a mantle of traditional legitimacy.

For approximately a century, from about 2100 to 2000 BCE, Ur was the capital of an empire known today as Ur III. During this time, as well as during the subsequent two centuries, Ur was an important port of trade linking Mesopotamia with the lands along the Gulf and beyond. The empire is also well known for its elaborate bureaucracy, as attested by the large number of tablets dealing with accounting matters that have been recovered from sites of this period. The city itself attained a size of at least 50 ha (124 acres).

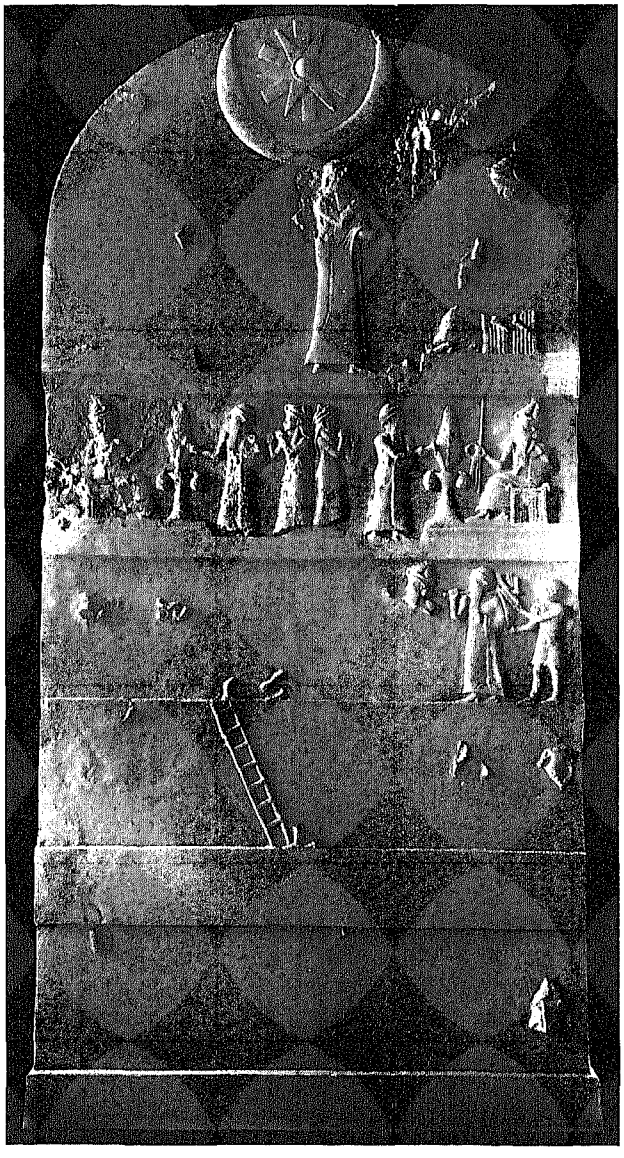
The first king of the dynasty, Ur-Nammu, began an ambitious program of building at Ur; what is known of this construction is confined primarily to the central religious area. Many of the buildings were finished or elaborated by King Shulgi, Ur-Nammu's son. Although the destruction of Ur by the Elamites at the end of the Ur III dynasty resulted in the razing of most of these buildings, the foundations provide an idea of the layout of the core of the city.

A large raised area, dubbed the Temenos by Woolley, was dedicated to the moon god, Nanna, and his wife, Ningal, as indicated by inscribed foundation deposits. Prominent within the Temenos was the ziggurat built by Ur-Nammu, on top of which the main temple probably stood, although no trace of it remains. The other buildings on the ziggurat terrace were badly destroyed at the end of the Ur III period but are thought to have served similar functions to those of the Early Dynastic period. The use of the Great Court of Nanna, a sunken court immediately in front of the ziggurat terrace, is unclear: Woolley's interpretation of it as a storage building for offerings brought to the temples has been challenged; it may have served as a place where the people of the city could approach the deities and the sacred symbols of them. Other buildings within the Temenos include the Ḫursag, possibly a palace; the Ganunmah (called Enunmakh by Woolley), which included a bank of storage chambers; and the Giparu, built over Early Dynastic remains of a similar building and serving as the dwelling of the *en*-priestesses as well as their burial place. Although there is little archaeological evidence for the Ur III city outside the

Temenos, there are indications that it was enclosed by a wall and surrounded by river channels or canals on all but its southern side.

The carved monument known as the stela of Ur-Nammu was found in pieces scattered around the ziggurat terrace (see figure 1). Large portions of it were not recovered, but the remaining fragments show scenes of Ur-Nammu receiving orders to build Nanna's temple and illustrations of animal sacrifice and musicians that may represent a celebration following the completion of the building project. The inscriptions on the stela include a list of canals built by order of Ur-Nammu.

Although much at least of the city's central area was destroyed in about 2000 BCE, presumably by invading Elamites, the city was soon rebuilt by the kings of the nearby city of Isin, who claimed to be the legitimate heirs of the Ur III state. Although Ur no longer served as the political capital, it functioned as an important religious and commercial center during the Isin-Larsa period (c. 2000–1760 BCE). The city reached its maximum areal extent of at least 60 ha (148 acres), and settlement in the immediately surrounding region seems to have peaked.



UR. Figure 1. *Stele erected by Ur-Nammu.* Dated to the third dynasty. (Courtesy ASOR Archives)

Excavations in the Temenos area provide testimony to the rebuilding of many structures within it. In various excavations around the city outside the Temenos, Woolley's work revealed residential quarters. Extensive exposures of domestic buildings were made in two central locations: the area known as EM, close to the southwestern edge of the Temenos, and the AH area, somewhat farther to the southeast. Numerous clay tablets found in the houses have been interpreted as indicating that the EM area was inhabited primarily by temple officials, whereas the occupants of the AH houses were more diverse. Both residential areas are composed of densely packed buildings separated by narrow, winding streets. The houses are typically built around an open central courtyard onto which most of the remaining rooms opened. Woolley argued that the houses contained two stories, a contention that has been challenged. Nearly half of the houses contain a room that appears, on the basis of its internal features, to have been used as a chapel. The functions of other rooms are more difficult to specify because of the infrequency of features or lack of information on where in the buildings artifacts were found. Nonetheless, the size, shape, and positioning of rooms shows considerable consistency among houses. Interestingly, fewer than 10 percent of the houses contain a clearly identifiable kitchen, indicating that cooking and baking must often have taken place outside the home.

Individuals of all ages were buried beneath the floors of the houses, in simple pits, clay coffins, pots, or brick tombs, accompanied by a range of pottery and jewelry, including beads, bracelets, finger rings, and earrings. Some individuals received greater wealth in grave offerings than others.

With the rise of Babylon in the eighteenth century BCE and continuing environmental degradation in southern Sumer, Ur's fortunes, as well as those of the other southern cities, began to decline. The city wall of Ur and many of the major public buildings were once again razed, this time following a major rebellion by the southern cities against Babylon's overlordship in about 1740 BCE. Nonetheless, the city remained occupied, and there is no indication of substantial destruction in the residential areas excavated. During the next few centuries people repaired and reused standing houses, rather than build new ones, and continued the practice of burying their dead beneath house floors. In about 1400 BCE, the Kassite king Kurigalzu restored many of the religious buildings in the Temenos area. Accompanying the

renewed building in the city was a proliferation of rural settlement.

Although the city remained occupied for another millennium, it seems not to have regained its earlier glory. A seventh-century BCE governor undertook restoration and some new building activities in the Temenos area, and the Neo-Babylonian kings Nebuchadrezzar (604–562 BCE) and Nabonidus (555–539 BCE) had the ziggurat, Temenos wall, and some residential areas rebuilt. However, not long after, in about 400 BCE, the city was abandoned.

SUSAN POLLOCK

URARTU. The highland state of Urartu stretched from the eastern bank of the upper Euphrates River to the western shores of Lake Urmia, and from the mountain passes of northern Iraq to the Caucasus Mountains. The kingdom dominated eastern Anatolia in the eighth and seventh centuries BCE. It is noteworthy historically for its rivalry with Assyria and archaeologically for its massive fortress architecture and sophisticated metalwork. For a time, Urartu was the strongest state in the Near East. Its distinctive and relatively uniform culture, much of it imposed from above, to judge from the royal focus of the surviving documentary and archaeological evidence, permeated this realm. Urartu's glories, however, were relatively short lived and were forgotten soon after the kingdom fell victim to a violent destruction in the late seventh or early sixth century BCE. Even the name of Urartu faded from view: it was transformed into Ararat by later vocalizations imposed on the Hebrew Bible.

Origins. The word *Urartu* is taken from Assyrian records, not from those of the Urartian people themselves, who called their kingdom Bianili. When it first appears in texts in the thirteenth-century BCE in the variant form Uruatri, the term has geographic rather than political connotations. It designates a land divided among petty kingdoms in the vicinity

of Lake Van. Neither archaeology nor textual records shed much light on the situation there until about the middle of the ninth century BCE, when evidence of increasing political consolidation appears concurrently with more regular Assyrian intrusions. By the late ninth century, Urartu was a single polity on the north and east shores of Lake Van, governed from a capital at Tušpa (modern Van) by a native dynasty that left cuneiform inscriptions of building and military activities in its own language.

The population over which this emerging monarchy extended its authority appears, on linguistic grounds, to have been autochthonous. The Urartian language is neither Semitic nor Indo-European; it is related to Hurrian, which itself is thought to have migrated from the very areas in which the Urartians later came to power into the northern fringes of Mesopotamia in the third millennium. The genetic relationship of Hurrian and Urartian is close, and most scholars now favor the theory that they are sister branches with a common parent. In recent years, a relationship with living northeastern Caucasian languages has been posited, although this remains controversial.

History. The debt that the creators of the kingdom of Van owed their Assyrian antagonists is exemplified by the inscriptions of the first of the royal line, Sarduri I (c. 830–c. 820 BCE): they are not only written in Akkadian but are virtually plagiarized from display inscriptions of Ashurnasirpal II. This cultural dependency diminished as Urartu entered a phase of rapid conquest under Sarduri's successors, Išpuini (c. 820–c. 790 BCE) and Menua (c. 790–775 BCE), who appear to have established the template for the empire. The frontiers were quickly moved outward to the banks of the Araxes River, to the western bend of the Euphrates near Malatya, and to the southern and western shores of Lake Urmia. Menua in particular was a prodigious builder. His surviving inscriptions dedicating temples, storehouses, and fortresses outnumber those of all other Urartian rulers put together. From bronze plaques, belts, helmets, vessels, and horse trappings (most found in illicit excavations but attributable to specific kings thanks to the cuneiform notations they bear), it is clear that the basic canons of Urartian art were already formed by this time.

The trajectory of Urartian expansion continued for most of the eighth century BCE under three rulers: Argišti I (c. 770–c. 750), Sarduri II (c. 750–c. 720), and Rusa I (c. 720–c. 713). The first two have left lengthy inscriptions in the form of annals, demonstrating that they, like Assyrian kings of the same era, campaigned annually, and sometimes even more often, harvesting booty that was presumably an important source of revenue in the royal economy. The territory the two added appears for the most part to have been in the north, in what is now the Republic of Armenia. In the second half of the eighth century BCE, Assyria, which had been in eclipse for decades, revived in time to thwart Urartian ambitions south of the Taurus Mountains. The most celebrated confrontation between the two powers, however, took place in 714 BCE, when Sargon II of Assyria launched a campaign into the northern Zagros Mountains and, after defeating Rusa in battle, invaded a portion of Urartu itself.

Sargon's depredations were not fatal to the kingdom, but the reign of Rusa I does appear to be a turning point in several respects. Intelligence reports to the Assyrian king reveal that Urartu was in turmoil: at least one revolt against Rusa had broken out, and Cimmerians, mounted warriors who were to wreak havoc among the more sedentary peoples of Anatolia for a generation, made their first appearance in history by inflicting a major defeat on Urartian forces. It may merely be a coincidence, but from this time onward, Urartian royal inscriptions become much less abundant.

Nevertheless, Rusa's successor, Argišti II, recorded conquests farther east than any of his predecessors; Rusa II, a contemporary of Esarhaddon of Assyria (680–669 BCE), created massive fortress-cities at Karmir Blur, Bastam, and Toprakkale—sites that are today the primary sources of information on Urartian material culture. During the seventh century BCE, Urartu and Assyria appear to have coexisted more harmoniously than previously.

The end of the kingdom is obscure. Virtually every site that has been excavated had been put to the torch, but neither agents nor the dates of the destructions have been unambiguously identified. The thread of Urartian chronology breaks after Rusa II because there are insufficient native documents to establish either the order or the number of kings. In the sixth century BCE, political control of the area passed first to the Medes and then to the Persians; the Armenians, linguistically unrelated to the Urartians, became the dominant ethnic group.

Aspects of the Civilization. The Urartian state exploited and reinforced the defensive potential of its mountainous territory by creating fortresses on the edges of alluvial plains. Although some settlements associated with these fortresses have been investigated, the archaeology of Urartu has largely been focused on defensive and administrative networks, not settlement systems. It may well be that considerable cultural diversity existed below this state-created level, which was, after all, quite rapidly imposed.

Urartian fortresses, however, were a major part of the economy. They contained massive storage facilities, attested by large pithos magazines and dedicatory inscriptions of storehouses whose capacities are given in impressive quantities of either dry or liquid measure. Some sort of redistributive system is implied by their prevalence.

The spread of the Urartian state also appears to have coincided with the introduction of irrigation agriculture in eastern Anatolia. The amount of land available for this was severely restricted by the terrain, and the kingdom was ultimately composed of approximately twenty isolated pockets in which population and agricultural production were concentrated. Some of the territory between these was exploited by pastoralists, but evidence for Urartian culture itself is concentrated in the alluvial pockets.

Urartian kings appear to have been almost perpetually engaged in construction activities, and the scale of their enterprise is astonishing, given the presumably limited resources of manpower at their disposal in this mountainous environment. The normal practice was to construct citadels on elevated ground, carving footings walls directly into bedrock. The basic construction material was mud brick, supported by stone socles. Both the thickness of the walls and representations of fortresses in art indicate that the structures were several stories high, capped by crenellated battlements.

Ashlar masonry was employed in special structures, most conspicuously in a distinctive type of tower temple that had a square, single-room ground plan with reinforced corners. Every one of the eight archaeologically known examples of these towers is located on high ground within a fortress, and was thus the product of royal architectural planning. The testimony of texts confirms that building temples and performing sacrifices at them was a royal prerogative and obligation, and with an emphasis that suggests a form of state religion. Although the Urartian pantheon consisted of hundreds of deities, including such venerables as the storm god Teišeba and the sun god Šiwini (important gods of the Hurrians), royal inscriptions and building projects focus overwhelming on a supreme god named Haldi, who is prominent only in Urartian culture.

The Urartian's stoneworking abilities are also manifest in rock-cut chambers. Cult niches, false gates as places of worship, and subterranean chambers and staircases were hewn out of living rock in all parts of the kingdom. The largest of these projects were royal tombs at Van, consisting of multiple rooms and numerous niches.

Among the majority of the population, the dead were laid to rest in more modest surroundings. There is some evidence of cremation, with remains placed in urn fields, as well as of simple interment. Illicit excavations of cemeteries have flooded the antiquities market with unprovenienced bronze objects, including horse trappings, weapons, plaques, and decorated bronze belts. On these, and on the modest number of objects of art that have been found in association with citadels, a fondness can be seen for animal motifs, floral decoration, and the anthropomorphic representation of deities astride lions and bulls. Urartian art lacks the narrative character of Assyrian palace art. While some reliefs of quite high quality are known, this does not seem to have been as favored a form of artistic expression and architectural decoration as it was south of the Taurus Mountains.

URBANIZATION. *See* Cities.

URKEŠ. *See* Mozan, Tell.

URUK-WARKA, ruined ancient city in southern Iraq, situated about 35 km (22 mi.) east of a main course of the Euphrates River, which flows through the provincial capital of Samawa (coordinates of ziggurat at Uruk: 31°19′18.5″ N, 45°38′25.6″ E). The name *Uruk* is the Akkadian rendering of a pre-Sumerian toponym UNUG, Erech of the Hebrew Bible (*Gn.* 10:10; *Ez.* 4:9). The modern name of Uruk is Warka.

The first excavator of Uruk was the Englishman William K. Loftus, in 1849 and 1853. About half a century later, the site was visited by Robert Koldewey, the excavator of Babylon (1899–1917). In 1912 Koldewey, acting for the Deutsche Orient-Gesellschaft (DOG), entrusted the direction of an archaeological expedition to Uruk to Julius Jordan, who had previously worked with him at Babylon and at Aššur with Walter Andrae. [*See the biographies of Koldewey and Andrae.*]

Only one campaign could be conducted before the outbreak of World War I. Work recommenced in 1928: eleven campaigns were carried out under the direction of Jordan, A. Nöldeke, E. Heinrich, and H. J. Lenzen. Excavation was once again halted by World War II.

Work was resumed in 1953, under Lenzen's direction, through 1967, and then, until 1977, under H. J. Schmidt. R. M. Boehmer has directed excavations since 1980.

At the time Uruk was founded, the Euphrates and the Tigris Rivers had not yet joined to form what is now the Shatt al-Arab. [*See* Euphrates; Tigris.] The coast of the Persian Gulf was situated about 80 km (50 mi.) farther to the northwest than at present. Uruk lay in well-watered, marshy alluvial land, covered by a network of river tributaries. For thousands of years, reed and mud thus constituted the most important building materials at the site, to which every stone had to be imported.

Uruk was founded in the fifth millennium, specifically during the last (the fourth) phase of the so-called Ubaid period. Ubaid levels were reached in deep soundings in the middle of Uruk, in Eanna (Sum., "house of heaven"), as well as in the western part of the city, in the area of the Anu Ziggurat; the deepest layers are today under groundwater. [*See* Ubaid; Ziggurat.] Remains of a Late chalcolithic culture were found there, of which the remnants of monumental buildings are significant. They appear to be so-called *Mittelsaal* ("middle hall") houses, which probably served as cult buildings, and are situated at the base of the ziggurat that had existed in the building's earliest phases. The pottery, of which numerous sherds have been found, is often painted and, occasionally, is of very fine quality. Clay figurines of cattle and numerous fragments of sickles indicate a farming culture. [*See* Agriculture.]

Uruk first consisted of two cities—Uruk and Kullab. Adam Falkenstein (1941) proposed that Kullab was situated in the precinct of the ziggurat of Anu (the great god of heaven), Uruk farther to the east, in the area later called Eanna. During the Uruk period, at the latest, both areas were united to form the city Uruk. The Uruk period, which followed the Ubaid 4 period, was first identified as such in Uruk. In this phase the city was so important an entire phase of Early Mesopotamian culture was named after it.

The excavations in Eanna uncovered the remains of an advanced civilization that was the oldest altogether. Remnants were found of numerous buildings of monumental scale, which have been interpreted as cult or administrative buildings. One of the most ancient is the so-called Limestone *(Kalkstein)* Temple. Its foundation layers consist of slabs of limestone that had been quarried west of the Euphrates, some 80 km (50 mi.) from Uruk, at the western edge of the Arabian shelf. The temple belongs to Uruk level V (c. 3600 BCE). Among the other buildings probably belonging to this level are the so-called Stone Building *(Steingebäude)* and the Stone Cone Temple *(Steinstifttempel).* The former consists of two surrounding passages and one middle room with a central platform. It was situated at the base of the extended ziggurat of Anu (phases F–B); its function remains unknown. The latter is so far the oldest known water sanctuary of any city in Mesopotamia. All three of these buildings share the use of limestone; in the case of the Limestone Temple, very hard cast-lime masonry was employed. The lower part of the outer walls of this building, situated inside a temenos, were decorated with gray-black, white, and red stone cones, after which it was named. Temple buildings of the *Mittelsaal* type were erected on the ziggurat and repeatedly renovated. The latest building phase is represented in part by the White Temple, in some sections still 2.5 m high, its walls covered with white plaster.

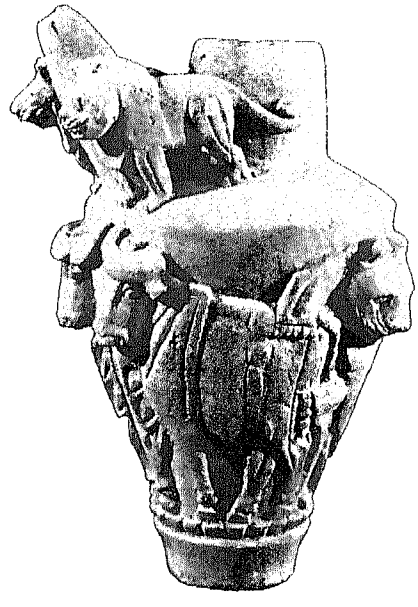
Construction activities flourished during the period of Uruk level IV, which was also characterized by numerous monumental buildings. In addition to small and large *Mittelsaal* buildings (e.g., buildings A, B [22 × 3.6 m], and C [54.25 × 22.5 m]) and *Hallenbauten* with occasional elaborate cone mosaics *(Pfeilerhalle,* or "hall of pillars"; *Rundpfeilerhalle,* or hall of round pillars", *Hallenbau*), there are unique building designs: buildings D and E; the subterranean Riemchen building (Riemchen are compact small bricks with a square section), which may have been laid out as a cenotaph and that was filled with a great number of cultural goods; and the Great Court *(Grosser Hof),* which

may once have been a garden. Carbon-14 dates from beams from temple C suggest a date of about 3500 BCE for the beginning of level IV, a finding supported by certain archaeological finds of Mesopotamian origin in Egypt at the time of Naqada IIc/d–III.

Beyond this grand architecture, there will have been private houses and a first city wall in this period at Uruk; their existence, however, has not yet been proven because of the city's enormous size (about 10 km, or 6 mi., in circumference), the depth of the archaeological layers (occasionally greater than 20 m), and because the excavators have concentrated their work in the city center. An indication for the existence of the city wall can be seen in a cylinder seal impression on a jar stopper from Uruk, excavated in Habuba Kabira. [*See* Seals; Habuba Kabira.] This seal impression demonstrates knowledge of the cylinder seal, which at the time probably developed from cylindrical beads decorated with incised geometric motifs and that, in its representations, immediately achieved high artistic quality.

Glyptic in this period consists, among other subjects, of heraldic scenes with mythical animals that are represented somewhat later in Egypt also: buildings (temples), the feeding of the temple herds, animal fights, lion hunts, and war scenes in which prisoners are taken.

Fine art also developed in other media: stone masons produced stone vessels decorated for the first time with basreliefs or with nearly three-dimensional figures; artisans even dared to use hard basalt (imported from northern Syria), for which figurative decoration for the most part had to be ground out, because copper and bronze tools were too soft for such work. Metal casting, already well known in the Ubaid 4 period, was employed not only to produce weapons and tools, but also small statues, using the lost-wax technique. [*See* Weapons, and Warfare.] Producing objects out of more than one element was particularly popular: for example, a limestone bull sculpture with silver legs and horns; stone vessels in which multicolored stone was used as decoration; and black-white-red or yellowish-gray mosaics covering the surface of clay or stone cones in patterns reflecting those of colorful reed mats. [*See* Mosaics.]



URUK-WARKA. *Decorated yellow sandstone ewer.* Proto-literate period; height, 8 in. Iraq Museum, Baghdad. (Scala/Art Resource, NY)

Pictorial representations are, in contrast to the Ubaid 4 period, no longer found on pottery. Mass-produced ware developed in the Early and Middle Uruk periods. The beveled-rim bowl, produced in molds and probably used as a rationing vessel or baking mold, was found in such numbers as to constitute a diagnostic ware of the Uruk period.

The development during the Uruk IV period of the so-called protocuneiform pictographic script represents perhaps the greatest achievement in early intellectual history. [*See* Cuneiform; Writing and Writing Systems.] It offers modern research a rich view of developments during the Archaic period. Precursors of writing were small clay and stone symbols, so-called tokens—a number of which were apparently transferred from three- to two-dimensional representation on clay tablets. [*See* Tablet.] Excavations at Uruk discovered far and away the greatest number of such tablets—indeed, the only known examples of texts from the earliest phase of writing came from this site. Uruk thus represents a unique center of early cultural development.

In the earliest script there is a sign—the pictographic representation—of a reed bundle, which later represented the goddess of love and war, Inanna (Sum., "lady of heaven"; Akk., Ishtar). She was, and remained until the end of Babylonian culture, the main goddess of Uruk. [*See* Babylonians.]

Late Uruk culture ends during the Jemdet Nasr period; it is represented at Uruk by level III. The following, so-called Early Dynastic period is, in its first phase (ED I), a time of radical change. Uruk was, as evidenced by numerous surface finds of pottery, even more intensively settled then than during the Uruk period. A mud-brick fortification wall (approximately 10 km long) that was, according to references in cuneiform literature, erected by Gilgamesh, enclosed the city. Remains of this wall are still visible. Little has been unearthed of the other construction works—merely houses and scant remains of monumental buildings. A high terrace was erected in Eanna. The population seems to have decreased in the ED II period. Scattered evidence points to settlement in only the western section of Uruk. The following ED III period left traces in the entire city, including in Eanna, where the terrace constructions were continued.

At the end of the ED III period, the sovereign of Uruk, Lugalzagesi, achieved rule over all of southern Iraq. This afforded him the power and means to commence an aggressive building program. The immense, so-called *Stampf-*

lehmgebäude ("pisé building") in Eanna—of which so far only foundations in an area of about 10,000 sq m have been excavated—and a large terrace in the northern part of Uruk are to be credited to his reign. It seems that both projects remained uncompleted, probably because the ruler was vanquished in a battle against Sargon of Akkad sometime around 2340 BCE. [*See* Akkade.]

After his victory, Sargon had the city walls of Uruk razed. He built his own Ishtar sanctuary, the Ulmash, in his city, Akkade. As a result, the cult of Ishtar in Uruk lost so much of its earlier significance it was merely administered part-time by the daughter of Sargon, Enheduanna. [*See* Cult.] Her main function was that of high priestess of the moon god Nanna in Ur. Lugalzagesi's monumental constructions were certainly also abandoned for this reason. Meager surface finds in Uruk suggest that there was a painful decline in the size of the population, which apparently only inhabited the northern half of the city. The Akkadian rulers paid tribute to Ishtar of Uruk just the same, as the fragment of a high-quality statue of a seated figure demonstrates. It is to be dated on stylistic grounds to the end of the reign of Sargon or to the reign of one of his sons—Manishtushu or Rimush. The statue may have been one of their sister Enheduanna's offerings in her priestly function.

The northern part of the city remained residential during the following Neo-Sumerian period. [*See* Sumerians.] After a short interlude, during which King Utuhegal of Uruk ruled Sumer, southern Iraq came under the rule of the kings of Ur. The first ruler of this dynasty, the so-called Third Dynasty of Ur, was Ur-Nammu. He pursued intensive building activities in Uruk (in Eanna the holy precinct of Inanna/Ishtar), in the course of which a ziggurat was erected over the Early Dynastic terraces. Up until the Seleucid period the precinct was repeatedly the object of more or less intensive construction. [*See* Seleucids.]

This empire collapsed in about 2000 BCE. Following a period of decline of some one hundred years, city rulers assumed control of Uruk in the early Old Babylonian period. One of these, Sinkashid, had a palace built for himself in the western part of the city that contained a peristyle court, one of the earliest known in the Near East.

According to the number and range of distribution of the surface finds in Uruk, the population was once again in decline; the primary residential area stretched from west to northeast. At the end of the eighteenth century BCE, settlement seems to have ceased altogether (no finds have been recovered from the second half of the Old Babylonian and the beginning of the Kassite periods). [*See* Kassites.] The reasons for this development are unclear; there was, in any case, no life-threatening change in climate because in neighboring Larsa the periods are well documented. [*See* Larsa.]

Settlement can be established only 250–300 years later in Uruk (c. 1450 BCE). The Kassite ruler Karaindash erected a small long-axis temple, dedicated to Inanna, in the eastern part of the ziggurat, that displays nearly life-sized mountain gods and water goddesses with vessels from which the water of life flows. This was a clear recollection of the original home of the Kassites, in the wet northeastern highland. The divinities, standing in niches in the outer facade, are made of molded bricks, a technique simultaneously employed in the eastern highland known as Elam. [*See* Elamites.] The selection of the settlement area also speaks for a new beginning at Uruk. It leaves the older areas in the northwest, north, and northeast untouched, stretching instead from the west through the southwest to the south. It can only be suspected that the primary temple precinct of that time is to be found below the Seleucid monumental structures Bit Resh and Irigal.

The population of Uruk in the period of the following Second Dynasty of Isin seems to have withdrawn to the confines of Eanna; clear evidence of settlement beyond this area is not known from that period. The Neo- and Late Babylonian periods once again witnessed more intensive construction work in Eanna—above all by the Assyrian kings Sargon II (710–705 BCE) and Esarhaddon in their function as rulers of Babylonia. Sargon built a new temenos wall around the ziggurat district (the first had been erected by Ur-Nammu), and the ziggurat was also renovated. Earlier, the Neo-Babylonian ruler Marduk-apla-iddina II (722–710 BCE) had erected, for Ningishzida, god of the nether world, a small temple east of the ziggurat, next to the Karaindash construction. Outside of the temenos were the houses of wealthy families. From the sixth and fifth centuries BCE of the Late Babylonian period the business associations of these families reached as far as Babylon. Settlement remains were found, moreover, in the southwest section of Uruk.

The Achaemenid period saw the steady continuation of Late Babylonian culture, which, in the Seleucid era, flourished again, despite Hellenistic influence, before it finally ceased to exist in the course of the Early Parthian period. [*See* Parthians.] There were, it appears, three rulers during the Seleucid period. The name of the first is unknown, and the second and the third bore a Babylonian name, to which they added a Greek name: Anuuballit Nikarchos and Anuuballit Kephalon. The casing of the ziggurat in Eanna, with mud bricks and a thin exteriors surface of baked bricks is, in all likelihood, to be credited to the first ruler, as is the reconstruction of an enormous mud-brick terrace (210 × 200 m) in the west, adjoining, on the southeast, additional terracing (90 × 80 m) and serving as substructure for a ziggurat. The two following rulers then erected two enormous temple complexes, one for Ishtar of Uruk (205 × 198 m) at Irigal and the other for Anu, who, with his wife Antum, was worshiped in the Bit Resh (213 × 167 m). This latter building lies close to the old Anu ziggurat, which then was connected to the terrace constructions (see above). That this building was a sanctuary of Anu is, failing any contradictory evidence, the very probable conclusion reached by Falken-

stein (1941). It is based on the spatial proximity of the building to the Bit Resh and on the idea of cultic continuity. [*See* Cult.] The type of construction (baked bricks) of this cultic building was very costly. It is not Greek, but rather represents the survival of the broadroom temple, known for almost two millennia in Mesopotamia. [*See* Temples, *article on* Mesopotamian Temples.] Greek influence may, on the other hand, be found in the minor arts—above all in the numerous terra cottas, in which Greek motifs replaced Late Babylonian ones, as was true as well of Babylonian glyptic. Two tumuli about 1.8 km north of Uruk contain Hellenistic furnishings; their opulence suggests that they contain the graves of the rulers of Uruk mentioned above. A third hill, about 2 km north of Uruk, which, because of its size, has not been examined, may also contain a tumulus—possibly that of the first of the three builders of the Seleucid period (see above). The clay-tablet archive of a priest found in Parthian houses in the southeastern part of Uruk contained, on the other hand, exclusively Babylonian, rather than Greek, cultic and prophetic texts, together with numerous administrative documents. [*See* Libraries and Archives.] Constructing these buildings certainly consumed enormous sums: the city's opulence can only be explained as a consequence of its position on a trade route going from India through the Persian Gulf to Greece.

After the Parthians conquered Mesopotamia, trade was blocked by an "Iron Curtain," and Uruk sank into oblivion despite the evidence of the presence of some wealthy citizens with richly furnished villas. [*See* Villas.] Babylonian culture died a slow death. The last known cuneiform tablet in the Babylonian language found in Uruk is from 108 BCE. The great temples of the Seleucid period fell into decay, and smaller buildings were constructed within them; a temple, whose ground plan corresponds to that of a temple erected in 111 CE in the southern part of Uruk, was built much later in the Bit Resh. Its type of construction is rooted in Roman architecture, and the inscriptions found in it are no longer Babylonian but Greek. The temple seems to have been built by merchants from the region of Mosul and dedicated to the otherwise unknown Gareus. Sea griffins are found as decorations on its capitals. The existence of this sanctuary may be understood as an indication of trade relations between the northern Mesopotamia/Mediterranean and Persian Gulf regions—the latter represented by apotropaic sea monsters. Beyond the temple precinct were workshops that produced glass and ceramics. [*See* Glass.]

Following the Parthian period, the Sasanians can be traced, above all in the southern part of Uruk, through finds of coins. [*See* Sasanians.] Such finds cease in the beginning of the fourth century CE. Activity in the workshops (see above) would have continued, but the Sasanian residential area lay to the southeast, outside of the city wall, well into the Late Sasanian period. A shift of an arm of the Euphrates in the eastern part of the city, farther to the east, may have forced the last inhabitants to abandon Uruk; they probably moved to a chain of hills, along a now no-longer visible watercourse (approximately 4 km, or 2.5 mi., east of the city), whose surface bore Sasanian material. The Sasanians attempted in vain to defend "al-Warka" in 634 CE against the assaulting Arabs; according to the archaeological record, al-Warka then did not designate Uruk itself, but presumably a tell about 4 km east of Uruk.

RAINER MICHAEL BOEHMER

V

VAUX, ROLAND DE (1903–1971), professor of history and archaeology (1935–1971) and director (1945–1965) of the École Biblique et Archéologique Française in Jerusalem. Roland de Vaux earned a *Licence ès-Lettres* from the Sorbonne and was ordained a priest before entering the Dominican Order in 1929. His first book (1934) revealed his talent for medieval research, but it was a 1933 article on the relationship between Adonis and Osiris that alerted his superiors to his potential as an orientalist. He was sent to Jerusalem in 1933 and lived there until his death. One of the last of a generation of scholars whose mastery of excavation techniques was matched by a sophisticated understanding of ancient documents, he made significant contributions to both biblical studies and Near Eastern archaeology.

De Vaux was one of the moving spirits behind the celebrated Jerusalem Bible, to which he contributed the annotated translations of *Genesis, Samuel,* and *Kings;* he also wrote the two-volume *Les institutions de l'Ancien Testament* (1958–1960), which has been translated into many languages. Its originality of conception was reinforced by the author's sure grasp of the evolution of Israelite religious and civic structures. De Vaux did not live to see the publication of the first volume of his life's work, *Histoire ancienne d'Israël* (1971). A second volume was extracted from his notes by François Langlamet. Unhappy both with the optimism of William Foxwell Albright, who, he believed, failed to recognize the complexities of the biblical text, and with the skepticism of Martin Noth, who, he thought, did not do justice to the archaeological data, de Vaux sought to find a middle ground by critically assembling all pertinent data. Remarkable for its control of primary and secondary sources, his history reflected the state of research at the time of its publication. Scholars have since become more cautious about the possibility of writing a history of the patriarchs or of the Israelite conquest.

De Vaux's first excavation (1944), the ninth-century Arab caravanserai at Abu Ghosh, was published as *Fouilles à Qaryet el-Enab, Abu Gosh, Palestine* (1950). From this apprenticeship he went on to excavate for nine seasons (1946–1960) at Tell el-Far'ah (North), which he identified as Tirzah, the first capital of the northern kingdom. [*See* Far'ah, Tell el- (North).] An able practitioner of the Wheeler-Kenyon method of excavation, his annual provisional reports in the *Revue Biblique* were models of description and judgment. He died before publishing a final report. His mastery of the field is, however, evident in his surveys of ancient Palestine in the Neolithic, Chalcolithic, and Early Bronze Ages (1970, 1971). Many of his articles were collected under the title *Bible et Orient* (1967).

Work at Tell el-Far'ah was interrupted by the discovery in 1947 of the Dead Sea Scrolls. G. Lankester Harding, then director of the Jordanian Department of Antiquities, entrusted de Vaux with the excavation of Khirbet Qumran. [*See* Qumran.] He completed the project in five seasons (1951, 1953–1956). In 1952 he excavated the caves in Wadi Murabba'at and directed the exploration of the caves in the cliffs north and south of Qumran. [*See* Murabba'at.] In 1958 he excavated at Khirbet Feshkha, a farm on the outskirts of Qumran. Preliminary reports of these excavations, which were indispensable in establishing the historical context of the scrolls, appeared regularly in the *Revue Biblique.* The nearest to a final report that de Vaux produced was his 1959 Schweich Lectures at the British Academy, London. First published in French (1961), a thoroughly revised and expanded text was eventually translated as *Archaeology and the Dead Sea Scrolls* (1973).

Once the quantity of textual material coming out of the Qumran area was recognized, de Vaux was invited to organize an international and interconfessional team to publish the documents. He solicited nominations from professional organizations and eminent scholars in Europe, England, and the United States and brought together a group as balanced as political circumstances permitted, both with respect to religion (four Catholics, three Protestants, and one Agnostic) and nationality (two French, two English, two American, one Pole, and one German). He contributed the archaeological section to each of the five volumes of *Discoveries in the Judaean Desert* that appeared under his general editorship.

VILLA. *Plan of a Roman villa.* Sepphoris, Israel. (Courtesy Joint Sepphoris Project)

VILLA. In the eastern provinces of the Roman Empire, the development of villas of distinctly Roman type—with mosaics, baths, and other luxury features—was less common than in the west. Throughout most of the Roman east the nucleated village (Gk., *kome*), not the villa, formed the principal unit of rural settlement. The building of Roman villas, where it did occur, was restricted mainly to suburban areas on the outskirts of major towns. Greek writers refer to these villas as *proasteia* or *kepoi* (lit., "gardens"), usually implying their association with small landholdings, especially vineyards and orchards.

The influence of Roman villa building can be seen at an early date in the Herodian palaces at Jericho and Herodium. Here Roman construction technology was used to create magnificent royal residences that included baths, colonnades, and halls decorated with imported marble and other luxury building materials (see Netzer, 1975, 1990). During the first centuries of Roman rule in the east, however, such an imitation of Roman villa architecture is rare. Few of the villas excavated in the eastern provinces have been dated earlier than the fourth century CE. Examples include second-century villas found near Ephesus and Antioch, and the recently excavated third-century villa at 'Ein-Ya'el near Jerusalem (for a discussion of the mosaics, see Roussin, 1993; compare the fine third-century mosaics from the "Roman Villa" at Sepphoris, for which see Meyers et al., 1992). Compared with many western villas these were not particularly luxurious buildings, but their marble columns, bathing installations, and mosaics reflect a growing taste for Roman technology and sophistication.

In contrast to these romanized suburban villas, most rural buildings in the eastern provinces preserved a strong regional character. On the Syrian plateau and in the hill country of Judea (Judah) survey and excavation have revealed the remains of numerous stone-built village houses and farms *(villae rusticae)* that belong to a distinctive, non-Roman architectural tradition. The recent excavation of two

utilitarian farm buildings (containing wine presses, stables, and storerooms) at Manṣur el-ʿAqeb near Caesarea provides further illustration of enduring local building practices in the countryside of the Roman east (for these excavations, see Hirschfeld and Birger-Calderon, 1991).

In the Late Roman period, following the transfer of Roman imperial power to Constantinople in the early fourth century CE, the evidence for Roman villas in the eastern provinces increases significantly. Written sources contain frequent reference to rich villas the imperial family built or acquired in the region of the new capital. These included several villas along the Bithynian coastline, as well as the great suburban palace at the Hebdomon on the Sea of Marmara. Built originally as a seaside villa by the emperor Theodosius, this celebrated imperial residence was extensively rebuilt by Justinian in the sixth century, with the addition of a new audience chamber and banqueting hall (see Thibaut, 1922).

The example set by the imperial family was emulated by the wealthy urban aristocracies. Late Roman sources tell of many senatorial families with elegant villas on the outskirts of Constantinople. Most of these villas included bathhouses and other luxury features; in one case a private hippodrome is attested. In his treatise the *Antiochikos* (Or. 11.234–239), the fourth-century orator Libanius talks admiringly of the many rich villas and gardens that existed at Daphne, a hilltop suburb of Antioch. A contemporary suburban villa of typical Greco-Roman design is described in a letter by Gregory of Nyssa. This villa, located in the Roman province of Galatia, combined an elegant colonnaded interior with a strongly built and turreted exterior designed primarily for security purposes.

The evident Late Roman boom in villa building in the east hinted at in the written sources is supported by a growing amount of archaeological evidence. At Antioch, excavation has revealed several fine Late Roman villas in suburban locations, including the richly decorated villa at Yakto (see Lassus, 1938). Traces of luxury villas have also been noted in the suburban zone around Roman Beirut. A more rudimentary type of villa is represented by recent discoveries at Jalame near Haifa. There the remains of a fourth-century rural building include hypocausted floors and a mosaic-lined wine press. The site also produced considerable evidence for glass making, suggesting an important additional component of the local villa economy (see Weinberg, 1988).

J. J. ROSSITER

VILLAGES. The most characteristic form of rural settlement across Western Asia from the beginning of settled life down to the present day has been the village. It has formed, with towns and cities, an essential part of the settlement hierarchy. Many of the fundamental aspects of village life were first established by the people of ancient Western Asia and persisted there over a very long period of time.

Geographers define villages as clusters of five or more households, whose inhabitants are primarily engaged in agriculture and related pursuits. Villages usually contain a few workshops run by specialist artisans, and some of their inhabitants may conduct a little commerce. There are some modest distinctions of wealth and class among the inhabitants. Provision for religious needs often takes the form of a building constructed especially to accommodate rituals and ceremonies. Villages are located adjacent to good arable land with access to a regular supply of water. The villages of ancient Western Asia possessed several of these features, though not all were present at the beginning.

Villages across Western Asia had a characteristic form and structure that took shape at the inception of settled life more than ten thousand years ago. They were always nucleated—consisting of a tight cluster of houses with only narrow lanes

between them and with few open public spaces. Nucleated villages are typically found in regions with few water sources, which obliged groups of people to build their houses close together near a spring or well. Such villages were relatively easy to defend, even without the protection of a circuit wall. Few villages in Western Asia had walls, but many needed the protection against marauding pastoral nomads such the dense agglomerations of buildings afforded. Some farming activities—preparing the soil for planting, animal herding, and constructing irrigation works—historically were performed by the community as a whole; and the village itself held some of the land adjacent to it in common. In such communities authority over access to land, water, and grazing rights was vested in a governing body or an individual. These villages were essentially self-sufficient in the necessities of life, but also participated in a larger world through their relations with nearby towns. They provided the towns with their surplus of food and their craft products, receiving in return goods not made in the village. At times of strong government, they were subject to a central political authority and owed it tribute.

Traditional village houses were built of locally available materials—stone in the uplands and mud brick on the plains. The rooms were often quite small because they were used mainly for sleeping and eating. The warm climate encouraged people to conduct most of their other activities such as food preparation, cooking, and crafts out-of-doors, in walled yards alongside their houses. It was there, too, that they kept their livestock and stored their crops. There was a sharp distinction between the private activities of the household within its walls and the public life of the village beyond. Traditionally, the household was the women's domain, while the men worked the fields and tended the livestock, with help from the women and children in labor-intensive times such as the harvest. The basic social and labor unit was the household, but lineage affinities were also an essential feature of traditional village societies in Western Asia.

The origins of these villages and their distinctive way of life lay in the first sedentary settlements formed by Epipaleolithic hunters and gatherers toward the end of the Pleistocene epoch. One of the oldest of these was a hut for a single household built at 'Ein-Gev on the east shore of the Sea of Galilee by people of the Kebaran culture, about sixteen thousand years ago. [*See* 'Ein-Gev.] The first true villages were established during the twelfth millennium BP (based on uncalibrated C-14 determinations). At 'Ain Mallaha, a site of the Natufian culture, in the Upper Jordan Valley, and at Abu Hureyra on the Middle Euphrates River. At 'Ain Mallaha a series of circular huts was set close together on a hillside near a spring. The Epipaleolithic village of Abu Hureyra 1 was composed of a series of multiroomed pit dwellings roofed with timber, branches, and reeds, later replaced by aboveground huts. Inhabited for one thousand five hundred years, this site was one of the first permanent villages established in Southwest Asia. Both settlements were inhabited by hunters and gatherers, demonstrating that village life began before the inception of farming.

The development of agriculture based on cultivated crops and herds of domesticated animals about 10,000 BP provided a firm economic basis for settled life. New villages were founded all across Western Asia, and they remained the predominant form of settlement for three thousand years. These Neolithic villages were much larger than those of the Epipaleolithic era, an indication of the growth in population that took place following the adoption of farming.

The houses in the earliest Neolithic villages were round or oval, with one or more rooms. These structures, architecturally similar to the huts found on Epipaleolithic sites, have been found in villages from Pre-Pottery Neolithic A Jericho in the west to Mefa'at on the eastern fringe of Mesopotamia. [*See* Jericho.] They seem to have been lived in by extended families. Later, the round houses were replaced by rectilinear ones with multiple rooms. It was a relatively easy task to extend such a structure, so the house could be expanded to accommodate a growing family. Diana Kirkbride (1966) and Brian Byrd (1994) have documented the change from round to rectilinear houses at Beidha in about 9000 BP and identified a large building in the center of the village that the community used for meetings and other events. [*See* Beidha.] The people of Jericho constructed a large stone wall around the village, in part for defense, and a stone tower inside, the earliest monumental architecture in the world.

The society of these early villages was largely egalitarian, with no individual enjoying significantly greater wealth than another. Burials under the floors of houses and special treatment of skulls suggest that people throughout the Levant and in Asia Minor revered their ancestors and believed in an afterlife. Special buildings for the dismemberment of the dead found at Çayönü and Nevalı Çori in southeast Asia Minor provide the earliest evidence for the construction of ritual buildings. [*See* Çayönü; Nevalı Çori.]

The inhabitants of these early villages engaged in some minor exchange of exotic goods, mainly obsidian from Asia Minor, other stones, and marine shells. Once pottery began to be made, in about 8000 BP, it too was exchanged. Such traffic, albeit on a modest scale, enabled these communities to maintain social contacts with each other that facilitated, for example, obtaining marriage partners. These contacts became more regular once the first towns developed after 7000 BP. The foundation of true urban settlements in the Halaf and Ubaid cultures (e.g., at Tell Ḥalaf in the northern Jezireh and Eridu and Tell 'Uqair in southern Mesopotamia) marked the emergence of a settlement hierarchy that persisted into modern times. [*See* Ḥalaf, Tell; Ubaid; Eridu.] Trade in pottery, obsidian, and, doubtless, perishable goods increased between the villages and these new towns; however, each village continued to be self-sufficient in food.

During the historical periods, the density of rural settle-

ment waxed and waned according to political circumstances and fluctuations in rainfall. In times of political stability village life could prosper, but when order broke down it might be severely disrupted. Similarly, a series of dry years could lead to a sharp regression of villages along the extensive margins of the dry farming zone. Thus, numerous villages on the Middle Euphrates River were inhabited during the Early and Middle Bronze Ages, but settlement sharply declined during the Late Bronze Age into the Iron Age; it seems that during the episodes of Mitannian and Hittite supremacy, rural settlement faltered. Numerous villages were founded in Roman and Byzantine times—two of the high points of rural settlement during the lengthy period of human occupation being considered here; many of those villages were abandoned during the decline of village life that took place as the Byzantine hold on Western Asia weakend.

The advent of urbanism created conditions in which institutions and individuals could acquire extensive estates farmed by a dependent peasantry, for example in Mesopotamia during the Ur III and Old Babylonian periods, on the ʿAmuq plain during the eighteenth century BCE, and in the extensive later domains of the Sasanian kings. The villages that housed those farmers were relatively impoverished, with little in the way of community facilities. Villages that controlled their own lands, especially in the more fertile regions, were more likely to enjoy a degree of prosperity.

One of the more distinctive features of Western Asia today is its mosaic of peoples: villages adjacent to each other may be inhabited by different ethnic groups with noticeably different material goods. Given the movements of peoples recorded in historical documents from earlier periods, it is likely that this pattern has ancient roots and may account for the differences in artifacts sometimes noted between contemporary sites.

The most striking element of village life in Western Asia is, however, its extraordinary continuity. The houses excavated in the Neolithic village of Abu Hureyra 2 on the Euphrates (c. 8000 BP) are similar in external shape and in many details of construction to those found in the region today. Similarly, the large, multiroomed dwellings found at the Ubaid site of Tell Madhhur in the Hamrin basin in eastern Mesopotamia inaugurated a type of house plan that was to remain typical of villages there into modern times. The farming economy on which the villagers themselves depended almost from the beginning—the cultivation of wheat, barley, and legumes and the raising of domestic animals (notably sheep, goats, and cattle)—has remained the basis of rural life.

A. M. T. MOORE

VINCENT, LOUIS-HUGUES (1872–1960), professor of archaeology at the École Biblique et Archéologique Française in Jerusalem (1895–1960), characterized by William Foxwell Albright (1961) as "the unrivalled master of Palestinian archaeology." Vincent entered the Dominican

Order in 1890. The following year he was sent to Jerusalem, where he remained until his death.

Born with an artist's eye for architectural features, quick to appreciate the significance of the ceramic typology formulated by Sir William Flinders Petrie in his excavation of Tell el-Hesi in 1890, and assiduous about visiting every type of excavation, Vincent was admirably equipped to write the first scientific synthesis of the results of Palestinian archaeology (1907). Thereafter, in more than two hundred articles in the *Revue Biblique,* he reported and critically evaluated every new excavation.

Such mastery made Vincent "tutor of all" (Albright) the new archaeologists who came to Palestine after World War I. In 1922, John Garstang, director of the Mandatory Department of Antiquities, invited him to be a member of the committee that officially fixed the division and names of the archaeological periods for ancient Palestine.

Vincent recorded the incidental finds of Montague Parker's hunt in 1909–1910 for the Temple treasures on the Ophel ridge (1911) as well as the discoveries made beneath the Ecce Homo Convent in Jerusalem (1933). His own excavations at ʿAin Douq (1920) and Emmaus (Amwas)/Nicopolis (1932) were no more than salvage operations because of lack of funds. His enduring achievement is the series of massive studies of monumental complexes in Bethlehem (1914), Hebron (1923), and Jerusalem (1912–1926, 1954–1956). Though subsequent investigations have inevitably imposed corrections, these volumes remain indispensable because of the quantity of data they assemble, their record of what has since disappeared, and the integration of textual data supplied by F.-M. Abel.

JEROME MURPHY-O'CONNOR, O.P.

VIROLLEAUD, CHARLES (1879–1968), French epigrapher of cuneiform. After studying history, geography, and Semitic languages in Paris at the Sorbonne and the École des Langues Orientales Vivantes from 1897 to 1900, Virolleaud set out to copy cuneiform tablets from Nineveh in the British Museum's collection and, later, in Istanbul, Sumerian tablets from Lagash. While teaching at the Université de Lyons, he published his work on Chaldean astrology (1905–1912). He visited Anatolia in 1909 and spent 1913 in Persia. From 1920 on, he was in charge of the antiquities department France had organized in Lebanon and Syria. In 1928 the discovery of a tomb at Minet el-Beida, which led to the identification of Ras Shamra with Ugarit, gave an unforeseen direction to his scientific activity: in 1929, Claude F.-A. Schaeffer entrusted him with a number of tablets written in an unknown cuneiform writing. Without waiting until he had deciphered the writing, and with the language the writing recorded also unknown, he put the texts at the disposal of specialists (Virolleaud, 1929, pp. 304–310). After examining the texts he arrived at several conclusions: he observed that the small number of symbols indicated an alphabetic system; that words so brief did not include vowels; and that the first sign of inscriptions on bronze objects might indicate that they were votive in nature. Influenced by his observations and also by the tomb's Mycenaean affinities, he at first thought he was working with an Aegean language. On 1 and 5 of October and on 8 December 1930, the identifications contributed by Hans Bauer, Virolleaud, and Édouard Dhorme, covering the entire alphabet, resulted in the full decipherment of the Ugaritic alphabet. Virolleaud became director of studies of the fifth section (religious sciences) of the École Pratique des Hautes Études in Paris, where his courses were based on newly discovered texts until the end of his career.

PIERRE BORDREUIL

Translated from French by Melissa Kaprelian

VITICULTURE. Archaeobotanists have sought the earliest evidence for cultivation of the grape vine (*Vitis vini-*

fera L.) within the zone where its wild ancestor (*Vitis vinifera* subsp. *sylvestris*) occurs naturally: southern Europe, along the northeastern Mediterranean and Black Sea coasts, inland across northern Syria and southern Anatolia, and into the Caucasus and Central Asia (Zohary and Hopf, 1993). Although the wild vine would have grown primarily in relatively moist riparian environments, vineyards, irrigated and not, have extended its range.

Through cultivation, grape seeds tend to become thinner, but the wild and domestic types (*Vitis vinifera* subsp. *vinifera*) cannot be definitively distinguished on morphological grounds alone. Archaeobotanical evidence for cultivation therefore also includes occurrence on archaeological sites of grape seeds in substantial quantities and of the charred wood of the vine (the latter more likely to reflect discarded pruned branches than firewood collected from the wild).

Applying these criteria, the earliest archaeological examples of grape were most probably collected from the wild. Few in number, they date to the Aceramic Neolithic, more than nine thousand years ago (e.g., from Çayönü, Aswad, and Jericho). [*See* Çayönü; Jericho.] Cultivation of the vine seems to have begun during the fourth millennium in Southwest Asia (Zohary and Hopf, 1993). Grape-growing and wine-producing sites dating to the end of that millennium are found in Egypt. By the mid-third millennium, viticulture had spread throughout Southwest Asia and beyond. It is in archaeological deposits from that time that concentrations of seeds are found from the Mediterranean to eastern Iran: for example, in burial offerings at Bab edh-Dhraʿ, Jordan, and Shahr-i Sokhta, Iran. [*See* Bab edh-Dhraʿ.] Evidence of the growing importance of the vine appears in the high frequency of grape seeds in archaeobotanical samples from third-millennium deposits at Kurban Höyük, Turkey. Also at that site was a large pit containing many charred seeds, stems, and fruit remains of the grape. A high concentration of mineralized grape seeds in a cess deposit at Malyan (c. 2000 BCE), in southern Iran, is probably the best direct evidence that the fruit was eaten (Miller, 1991). [*See* Malyan.]

The earliest evidence for wine comes unexpectedly from Godin, in western Iran (late fourth millennium), where residues of tartaric acid were identified from distinctive jars (McGovern and Michel, 1994). [*See* Godin Tepe.] It is known from later texts that where the vine was an important cultigen, its primary use was for wine production. However, viticulture was even practiced by the irrigation civilizations of lower Mesopotamia, where the grape and its products (like syrup) seem to have remained specialty items (Powell, 1994).

In addition to the archaeobotanical, chemical, and textual evidence for viticulture, the vine is depicted in the art of ancient Southwest Asia, appearing, for example, on a few Elamite (c. 2000 BCE) sealings from southwestern Iran. By Assyrian times, images of vineyards around besieged cities were used symbolically to distinguish landscape from wilderness.

The products of the vine have many culinary uses whose cultural significance extends beyond their immediate dietary value. Grapes, raisins, and grape syrup should not be underestimated as sources of sweeteners for peoples who did not have many ways of getting quick and tasty calories (Powell, 1994). In addition, wine vinegar can be used in preserving food. The vine was (and continues to be) most important in wine making, however.

It is difficult to identify the technology associated with small-scale wine production. The stoppered jars in which wine residues were found at Godin were particularly suited to their storage task: clay "rope" designs applied to the outside of 30- and 60-liter vessels would have prevented rolling, which suggests that they may have been stored horizontally (Badler, 1994). No grapes were found in the archaeobotanical samples, however, and no wine-pressing installation was excavated. Grape cultivation on a large scale, at least in the Levant, seems to be associated with wine production as early as the third millennium (Early Bronze Age), when grape presses are carved into bedrock (Stager, 1985).

Wine became the primary drink in the eastern Mediterranean region for social as well as religious occasions. As grapevines take several years to mature, the development of viticulture on a large scale requires social stability. Lawrence Stager (1985) suggests that in the Levant widespread adoption of viticulture and wine production are associated with that development as early as the Early Bronze Age. By Late Antiquity, it had become a major trade item as well in those areas with access to relatively cheap sea transport (McGovern et al., 1994). In contrast, wine is scarcely mentioned in Mesopotamian texts until the Middle Bronze Age, when those societies came increasingly in contact with the Levant. In Mesopotamia, therefore, wine seems to have been restricted to luxury or religious contexts (Powell, 1994).

VITREOUS MATERIALS.

[*This entry surveys the history of vitreous materials with reference to the technologies used to create them, the uses to which they were put, and their overall role in the cultures and societies in which they figure. It comprises four articles:*

Typology and Technology
Artifacts of the Bronze and Iron Ages
Artifacts of the Persian through Roman Periods
Artifacts of the Byzantine and Islamic Periods

The first serves as a general overview, while the remaining articles treat the artifacts of specific periods and regions. For related discussion, see also Glass.]

Typology and Technology

The term *vitreous materials* encompasses a range of artificial glassy and glazed materials. In addition to glass in the generally accepted sense, it includes materials as diverse as pottery glazes and Egyptian Blue, a synthetic pigment that may contain a negligible proportion of glass. These materials are grouped on the basis of a number of rather loose criteria. First, they are silicates, the products of high temperature processes, or pyrotechnologies, which cause the production of a certain amount of glass in the material. Second, they are typically not clay based, although they may be associated with fired clay material, as in the case of pottery glaze. Finally, in Near Eastern archaeology, early vitreous materials tend to be based on the chemical system soda-lime-silica (Na_2O-CaO-SiO_2). Some vitreous materials based on mixtures of lead oxide and silica were introduced but, before Islam, their importance tends to have been peripheral.

Among the particular difficulties in dealing with vitreous materials is the problem of identification. Typically high-fired, fine-grained, and glassy—commonly with a layered structure which may hide the nature of the core and often turquoise or blue in color—there has been confusion between the various frits and faience, with blue minerals such as azurite, and with glazed and fired clay bodies. The problem is compounded by weathering, which may dramatically modify color and morphology, as well as remove glaze layers, completely eliminating the original characteristics. Recourse to scientific techniques such as microscopy and X-ray diffraction may be necessary if an accurate and unambiguous identification is to be made. [*See* Microscopy; X-Ray Diffraction Analysis.]

Terminology. Because the application of some terms contradicts modern technological practice, the terminology of early vitreous materials has been found to be wanting. However, terms such as *frit, faience,* and *glassy faience* are used in numerous important publications, and to abandon them now would only add confusion to an already troubled area. The current consensus of understanding, follows.

Glass. A glass is a material which was formed in the molten state and cooled sufficiently rapidly so as to retain the disordered structure of a liquid. While modern glass is commonly colorless and transparent, early glass was commonly colored and often opaque; it was intended to imitate precious and semiprecious stones such as turquoise and lapis lazuli. These effects were achieved by the solution of colorant metal ions in the glass and the addition of an opacifier, which by producing a dispersion of fine particles, inhibits the transmission of light.

Glaze. A layer of glass which coats another material is a glaze. In an early Near Eastern context, glazes may be found on stones, particularly steatite (talc) or quartz, on frits and on clay-based pottery, brick, or tile. [*See* Tile.]

Frit. A frit is a polycrystalline body (i.e., it is composed of many crystalline grains) which has been heated so that it sintered (the constituent grains adhered as a result of localized melting at their points of contact). Such frits are commonly porous and relatively weak and friable because of the low degree of melting. Two types of frit, faience and Egyptian Blue, are commonly encountered.

Faience. A composite material, faience is composed of a sintered quartz body with an overlying glaze. A sintered quartz body without glaze can be found and may not, strictly speaking, be termed faience. However, faience glazes are thin and readily removed by weathering; it may be extremely difficult to determine if an object now of sintered quartz was originally faience in the strict sense of the term. Closely related to faience in composition and structure is stonepaste, a quartz-rich frit body developed by Islamic potters late in the first millennium CE. Other, less common categories of vitreous material include glassy faience, essentially a glassier variety of faience body, but with a distinctive composition.

Egyptian Blue. A synthetic copper calcium silicate ($CuCaSi_4O_{10}$, equivalent to the natural mineral cuprorivaite), Egyptian Blue commonly occurs intimately mixed with quartz (a raw material which has not completely re-

acted), sometimes along with a certain amount of glass formed in firing. Also distinguishable are pale-blue and green frits, high-lime/low-copper relatives of Egyptian Blue which are glassy or have crystalized a pale calcium silicate rather than the deep-blue copper calcium silicate characteristic of Egyptian Blue itself. However, unambiguous identification of these depends on physicochemical methods.

In view of the difficulties in identification, P. R. S. Moorey (1994) points to the benefits of a purely descriptive terminology based on macroscopic features: glazed composition for faience and faiencelike materials and unglazed composition for fritlike materials where a glaze may not be unambiguously identified. Such an approach is to be prefered to guesswork, where it is not possible accurately to characterize the materials concerned.

Raw Materials. Silica, the major constituent of glass, is found almost everywhere in the form of quartz sand or pebbles of quartz or chert; however, the melting point of the pure material, at around 1700°C, is substantially above the temperatures that were attainable in preindustrial kilns and furnaces. The production of vitreous materials depends on the dramatic fluxing effect of alkalis and lime on this high melting temperature. The admixture of a few percent alkali will allow a substantial amount of melting at temperatures well below 1000°C; about 20 percent will allow complete melting and the formation of a glass at these relatively moderate temperatures.

Two sources of alkaline flux appear to have been used by early Near Eastern craftsmen. The most widely available was the ash produced by the burning of plants that grew in saline (desert) environments. In addition to soda, these plant ashes contain substantial amounts of potash, lime, and magnesia. The alternative source of alkali was natron, a naturally occuring mineral soda (the trona of geologists). The only major natron deposit currently recognized as a source for the ancient Near East is in Wadi Natrun in Egypt. Natron is a relatively pure form of soda and lacks the impurities characteristic of plant ash. Chemical analyses may therefore provide an indication of the alkali source used—natron-based materials having low potash and magnesia relative to soda.

Pure alkali silicate glasses are soluble in water; a glass or glaze must contain some lime (calcium oxide) as well, to render it stable. It is believed that lime was not usually deliberately added to early vitreous materials as a separate ingredient; instead, it was included incidentally, as a component of either the flux or the sand. In order to make a successful glass or glaze using a pure natron, a calcite-bearing sand was introduced as a source of both silica and lime; the use of a plant ash provided sufficient lime with the alkali to allow the use of a relatively pure silica source such as crushed quartz pebbles.

Manufacture and Fabrication. Archaeological evidence for the manufacture of faience, frit, and glass from their raw materials is rare; where reported, it has, on the whole, proved less enlightening than might have been hoped. Most of what is understood depends on ethnographic observations of traditional crafts, analysis of the materials themselves, experimentation, and the interpretation of limited textual evidence.

A faience body was prepared from very fine crushed quartz or sand bound by water, probably with a small amount of gum. It could be modeled using simple tools and by the New Kingdom period in Egypt was being pressed into open-face molds. While a pure quartz body lacked the plasticity to allow it to be thrown on a potter's wheel, it has been suggested by Pamela B. Vandiver (in Kaczmarczyk and Hedges, 1983) that in Ptolemaic times a small amount of clay was introduced to allow vessels to be thrown. Three methods of glaze application were possible: (1) by mixing alkali with the body when wet, which migrated or effloresced to the surface as the body dried (on firing, the alkali-quartz mixture at the surface reacted to form a glaze); (2) by burying the shaped faience object in an alkaline glazing mixture which, on firing, reacted with the body to produce a surface glaze layer by a process termed cementation; and (3) by applying a raw glaze mixture or already fritted glaze to the surface. Evidence for all three approaches—efflorescence, cementation, and application—has been reported from the examination of faience artifacts. Colorants were added to the glaze mixture or to the body itself, as finely divided pigment particles or as colored frit or glass. Some of these moved to the surface as the object dried, producing a strongly colored layer. Surface coats or slurries of colored body material could also be added and polychrome effects achieved by the inlay of colored body material. The systematic study of the decorative techniques used in faience production is in its infancy, however.

Egyptian Blue appears to have been formed from a mixture of calcite-quartz sand, copper oxide, and a small amount of alkali. The presence of small amounts of tin or arsenic in some of the material suggests that the copper source was scale formed by heating copper-metal scrap. Upon firing, the calcium and copper oxides, with a proportion of the quartz, reacted to form the Egyptian Blue compound. The alkali formed small amounts of a melt phase which helped the reaction proceed faster and at lower temperatures. The color of the Egyptian Blue depended on the grain size of the crystals formed and their concentration. In turn, this depended on controlling the proportions of raw materials, the degree of grinding, and any repeated grinding and refiring of previously fired material. Like faience, Egyptian Blue could be molded or worked into shape in an unfired state; alternatively, it could be worked after firing. In addition, it was crushed and used as a pigment in mural painting and pottery decoration. [*See* Wall Paintings.]

Experimental replication suggests that the firing temperatures of frits such as Egyptian Blue and faience were similar—in the range of 850–1000°C. Durations were probably of the order of hours, as opposed to days or minutes. Firing

atmospheres were generally oxidizing, as copper is almost invariably in an oxidized, blue state. These conditions are typical of those that were used to fire pottery kilns throughout the Near East. The development and production of frits and faience did not depend on special or extreme kiln or furnace regimes, but rather on the skilled manipulation of the materials used. The glazing of pottery or stone required temperatures similar to those used in firing faience, frits, and pottery itself. The examination of glazed steatite has shown that the glaze was applied by both the cementation and application approaches; on clay-based pottery, brick, and tile, the raw glaze mixture or a glaze frit would have been applied.

The production technology of glass is considerably more demanding. Although based again on a mixture of alkali and silica, the production of a fully molten, homogeneous melt which could be cooled to a glass would have required higher temperatures and longer melting times. A multistage process, involving preliminary fritting of the raw materials and intermediate crushing and grinding, may have been used. Manipulation of molten glass in the hot, plastic state, and the need repeatedly to reheat an object during the fabrication process (so that it could be continually worked), would have required specially designed furnaces with different characteristics from those used in pottery or metalwork. Glassmaking itself, when fully developed, is likely to have involved skills, procedures, and equipment considerably more sophisticated than those involved in the production of other vitreous materials.

Origins and Early Development. Early experiments with glazed stones are likely to have stemmed from observations of glazing which accidentally occurred when alkaline fuel ash reacted with pebbles or small worked-stone objects in a strong fire. By the mid-fifth millennium, small faience objects, with a core of crushed quartz, were widespread. Many early glazes are turquoise or blue, from dissolved copper; this association with copper has prompted speculation of a relationship between the development of the early vitreous materials industries and copper metallurgy. Direct evidence for such an association early in the Bronze Age is yet to be presented, although in the Late Bronze Age workshops producing vitreous materials were sometimes located close to those of metallurgical and other industries (e.g., Qantir, Egypt).

Small objects of a glass-rich material, typically colored blue and without a distinctive glaze layer, are known from a number of sites dating to the late third millennium. Although the results of detailed physical examinations of these objects have not been published, they appear to represent the earliest glass in the strictest sense. They were finished using cold-working lapidary techniques and are generally considered to have developed from the background of faience and glazing technology, where overfiring or poor compositional control are likely to have resulted in the accidental formation of glass from time to time. Egyptian Blue appears as a pigment in Egyptian wall paintings in the late third millennium, itself a product of the same technological background and consisting of similar raw materials combined in different proportions.

The appearance of the first glass vessels in western Asia in about the sixteenth century BCE marks a revolution in the fabrication of the material. These vessels were produced on cores of sand or clay. The core was coated by dipping it in a crucible of molten glass or by trailing molten glass onto it. Decoration was added by trailing molten glasses of various colors onto the surface of the vessel; it was made smooth by rotating it on a flat stone. The innovative element of this approach is in the manipulation of the glass in the molten state and the application of its plastic properties. Higher temperatures and novel furnace designs are likely to have been required. The color palette of glass was extended to include reds, greens, yellows, and whites, as well as blues, based on a range of metal oxides, including those of copper, cobalt, manganese, antimony, and lead. These colors were also applied to objects made of faience. Glazed pottery vessels appear at about the same time as the earliest glass vessels; the two developments are considered by many authorities to have been related.

Later Developments in Glass. The reemergence from the dark age at the end of the second millenium BCE saw the continuation of technologies for vitreous materials, but the major advances of the first millennium were in the field of glassmaking, rather than in faience or frit production. [*See* Glass.] Foremost are the changes which eventually allowed the development of the Roman glass industry on an unprecedented scale. One of the most important of these was a change in the formulation of glass which occured in the seventh or sixth century BCE. Up to that time, most glass had been based on a mixture of plant ash and crushed quartz—materials which had to be collected by foraging and which required labor-intensive preparation. The new approach involved the preparation of glass from a mixture of natron and sand. These were materials which could be quarried from virtually inexhaustible deposits and, furthermore, required minimal processing before use in the glass batch. This allowed a major increase in capacity, which fed the growth of the Hellenistic and Roman industries. The major source of natron appears to have been Egypt, although Pliny (*Nat. Hist.* 36.190) indicates that glass sand was obtained from near the mouth of the Belus River, near Haifa, in modern Israel. Recent excavations (Gorin-Rosen, 1995) indicate that, by the end of the Byzantine period, and perhaps considerably earlier, glass was being melted in large tank furnaces with a capacity of 8–10 tons on the Syro-Palestinian coast. From there it could be transported in broken or "chunk" form to wherever it was required.

A further development was in the ability to control the natural color of glass. After about the seventh century BCE,

it was found that adding small amounts of antimony to glass counteracted the green or blue coloration caused by iron oxides; from the second century BCE onward, manganese was used for this purpose. A further impetus to the industry was the development of glassblowing in Syria-Palestine late in the second half of the first century BCE. This development allowed substantial increases in the rate of vessel production. Furthermore, blowing allowed the production of very thin-walled vessels, which increased the number which could be produced from a given glass batch. Along with the earlier changes in glass composition, the introduction of blowing encouraged the production of large quantities of inexpensive, thin-walled, transparent tablewares and revolutionized the role of glass in society. Although in the eighth–ninth centuries CE in Syria and Egypt, glass production reverted to the traditional plant-ash alkali formulation, the techniques of blowing and decoloration by the addition of manganese continued through to the modern period.

Islamic Glaze and Ceramic Technology. From the Late Bronze Age through to the Islamic period, pottery glazes were soda-lime-silica compositions. Lead-oxide-based glazes were introduced in the Roman period, but they were not widely used and their potential was not developed. However, in the eighth or ninth century CE, in response to the fine ceramics being imported from China, Islamic potters in Iraq developed the technique of adding tin oxide to the pottery glaze, to make it white and opaque. The tin was commonly added with a certain amount of lead to an alkali glaze—or alternatively a lead-tin-silica-glaze formulation was used. At about the same time, Iraqi potters began to add glass and additional quartz to their pottery bodies. This new pottery body evolved into the so-called stonepaste or quartz-frit body, composed predominantly of quartz with some glass and clay. It is very similar to the faience bodies of earlier periods, although it appears to have developed separately. These innovations were taken up and developed by potters in other centers—in Egypt and Syria. They resulted in the production of nearly white ceramics, which were well suited for painted decoration in oxide colors and with luster, a fine metallic coat of silver or copper. The tin-glaze and luster techniques were the foundations of later medieval pottery industries in the West—in Spain and in Italy.

IAN C. FREESTONE

Artifacts of the Bronze and Iron Ages

The versatility of silicate technology made possible the development of many types of frits, glasses, and glazes with different carriers in the Bronze and Iron Ages. The most common were faience, glass, glazed pottery, glazed steatite, and blue composition ("Egyptian Blue").

Faience. Invented in the fifth millennium, probably in northern Mesopotamia, faience was one of the first synthetic materials. It consists of a crushed and moulded quartz (cf. silica sand) composition core with an alkaline glaze generated by efflorescence, cementation, or application techniques. Because simple alkaline glazes adhered so well to this carrier and ubiquitous quartz could be readily modeled, faience was the most popular vitreous material of the Bronze and Iron Ages. P. B. Vandiver and W. D. Kingery refer to it as "the first high-tech ceramic" (Vandiver and Kingery, 1986, p. 19). "Glazed frit," possibly to be equated with faience, is reported from seventh millennium BCE Jericho, but

VITREOUS MATERIALS: Bronze and Iron Ages. *Polychrome faience rhyton.* International style from Kition, Cyprus. Dated 1300–1200 BCE, height 26.8 cm. (Courtesy Department of Antiquities, Nicosia, Cyprus)

this seems inherently unlikely and requires scientific verification.

Tell Brak in northern Mesopotamia provides the clearest evidence for state-of-the-art faience production in the fourth millennium. Beads were incorporated into temple bricks, and zoomorphic seals or amulets—molded bears, ducks, hares, and monkeys—are extensions of a previously plain repertoire. In Egypt at that time, copper-colored blue glaze imitating semiprecious stone was sometimes decorated with black or brown glaze.

Although vessel formation existed in Mesopotamia and Egypt in the fourth millennium, regular production of these luxury products only began in the third millennium, when it also expanded to Elam. Vessels in Sumer were elaborated with incised and sculpted decoration. The repertoire also included seals, tiles, rods, figurines, mace-heads, and beards, the last two probably belonging to temple statues. New glaze colors—red, white, green, and possibly yellow—are attested for the first time in the north. A wagon model from a grave at Tell Bi'a in Syria also demonstrates precocious innovations in the north. While small beads became common, larger faiences remained prestigious: a cylinder on a metal rod figured in Mesannipadda's gifts to the king of Mari, and wall inlays may have been inserted in King Shulgi's mausoleum at Ur.

It is not certain if production existed in Syro-Palestine in the Early Bronze Age. Small disc beads, while fairly common, may have come from prolific centers in Egypt. The advent of faience on Cyprus and Crete, where industries subsequently excelled, may be historically correlated with a notable expansion of Egypt's maritime links with Byblos in the fourth dynasty (c. 2575–2465 BCE). In Mesopotamia,

during the Ur III period (c. 2112–2004 BCE), Akkadian terms sometimes identified with vitreous materials appear. However, their exact meaning and significance are controversial.

Centers of bichrome vessel production were established in the Levant and probably in Anatolia in the Middle Bronze Age (c. 2000–1550 BCE). Northern workshops supplying vases in native and egyptianized styles were probably attached to the royal courts, based on the evidence of both types of vessels in palaces and royal tombs. Faienceworkers, probably from Egypt, flourished at Byblos, where they equipped temples and royal tombs; another derivative industry in ancient Palestine created specialized cosmetic containers.

The zenith of western Asiatic faience production was in the later part of the Late Bronze Age (c. 1400–1200). Production is attested at Tyre, Beth-Shean, and probably Babylon, but workshops proliferated, some, perhaps, beyond the management of palaces and temples. Mass production of personal ornaments, cylinder seals, and vessels ensued. Polychromy, a belated adaptation of technological innovations made by glassworkers in the sixteenth century BCE, was widespread. Previously, faience imitated semiprecious stone, now inlaid metalwork. It was executed by direct glazing and overglazing, and so was a development independent of Egypt, where polychromy was effected by inlaying and outlining glazes. Carefully selected metal colorants yielded variants of blue, green, brown, yellow, white, gray, black, red, purple, silver, and, probably, transparent glazes. Another characteristic of this florescence is that, because a stylistic "koine" was established, it is difficult to pinpoint the sources of widespread faience artifacts. For example, distinctive female-face pendants with bitumen inlays, probably souvenirs from temples, are found from Cyprus to Susa.

Faience was used especially in temples and as funerary offerings. In the Ishtar Temple at Aššur, it was used for votive figurines and body parts, furniture inlays, and decoration such as amulets, bracteates sewn on robes, statue inlays, plain and figurative wall tiles and knobs, elaborate vessels, and other objects. Tassels may have belonged to equestrian harnesses, for which there are identical examples at el-Kurru in Nubia. Vessels found in the cemetery at Mari, in Syria, are typical of the Late Bronze Age. Their small size, narrow necks, and lids suggest that most had contained precious ointments or the like.

Of all the major regions in the Near East, only ancient Palestine, and perhaps Anatolia, does not seem to have had a vessel-production industry. Egyptian domination precluded local patronage of gifted faienceworkers. Canaanite rulers therefore looked mainly to Egypt for such luxuries. In addition, colorful faiences in the Fosse Temple at Lachish and the Ḥathor shrine at Timnaʿ may have been sent directly from there as votives. Canaanite faience assemblages reflect the Egyptian popularity of bowls with Nilotic scenes. These also reached coastal Syria and Cyprus, where copies may have been produced. In that region, eclectic craftsmen fashioned some of the choicest Near Eastern faiences by blending Egyptian, Asiatic, and Aegean styles and techniques. As shown by head goblets in the Uluburun shipwreck off of southwest Turkey, their products were sent abroad, probably to the west, where a derivative center may have been established in Late Mycenaean Greece.

In the Iron Age, following destructions associated with the Sea Peoples, faience production in the Near East waned considerably. Only in the highlands of Iran and Elam, in the twenty-fifth and twenty-sixth dynasties in Egypt, on Rhodes, and probably in Phoenicia were there innovating centers of production. Monochrome, mass-produced Egyptian and egyptianized amulets, beads, and scarabs increase throughout the Levant, but tenth-century BCE Phoenician expertise is most clearly evident in a set of vessels and figurines from Lefkandi in Euboea. Iranian production is noted for its polychromy; Egyptian for its delicate openwork beads, plain lotiform chalices, and chalices with scenic compositions; and Rhodian for a variety of small egyptianized cosmetic containers. The marked decline of faienceworking in Mesopotamia was the result of the impact of polychrome pottery.

Glass. Isolated finds of pre-sixteenth-century BCE glass are reported from Troy to Iran and Egypt, but the dates and composition of many are suspect. Safely stratified examples in graves, like a pinhead from Nuzi, a bead from Tel Dan, and several beads in composite necklaces from Dinkha Tepe, indicate the occasional use of glass, much of it as a by-product from faience and metalworking. Raw glass from Akkadian–Ur III deposits at Eridu, Tell Asmar, and Tell Brak is significant because it demonstrates intentional production (whatever the glass may have been used for eventually) and its relative frequency in Mesopotamia at that time. This phase in the history of glassmaking constitutes stage 1, a preadaptive phase in which the distinctive properties of glass were not exploited and its occurrence was infrequent and irregular. An Egyptian royal pectoral with blue glass inlays and purple ones fused to a plaster substrate and inlays from the tomb of King Ahotep (c. 1550 BCE) may also belong to this stage.

Profound technical innovations in vitreous materials occurred in about the sixteenth century BCE in northern Mesopotamia and northern Syria. Polychrome core-formed glass vessels, together with glazed pottery, appear then. The former exhibit new pyrotechnological skills distinctive of glass: fusing, coiling, trailing, and marvering. Multicolored bottles were made on a removable core of clay and dung in a manner recalling lost-wax casting in metal. That metalworkers were closely associated with this innovation, no doubt in conjunction with faienceworkers, is also indicated by the associated use of a range of metal oxides to achieve contrasting colors on the same vessels. This formative juncture in the history of vitreous materials, which equates with the start of stage 2 (working glass industries), took place at a time of political upheaval in northern Mesopotamia, a time when working practices of diverse craftsmen belonging to the earlier Amorite palaces were being reorganized. Their vessels are found in northern Mesopotamia and their cast nude-female plaques and spacer plates for separating strands of beads in necklaces as far afield as Greece.

Asiatic glassmaking innovations were probably transferred to Egypt during the expansionist reign of Thutmosis III. Soon, an independent tradition of elegant core-formed glass vessels was established there under royal authority. The Egyptologist W. F. Petrie retrieved detailed information on glass workshops at Amarna, whereas in western Asia the only evidence is indirect—cullet from Aššur and ingots from Alalakh and Tell Brak. The Brak ingots are from a Mitannian palace, so that there, too, glass production was under royal patronage. That it was internationally esteemed is clear from royal requests for specific colors, from its rank immediately below gold and silver in the representation of Thutmosis III's dedication of Syrian booty on a limestone relief from the Amun-Re temple at Karnak, and from the gold foil that liberally frames a glass pyxis found on Cyprus. Bead manufactories were far more numerous and perhaps differently organized.

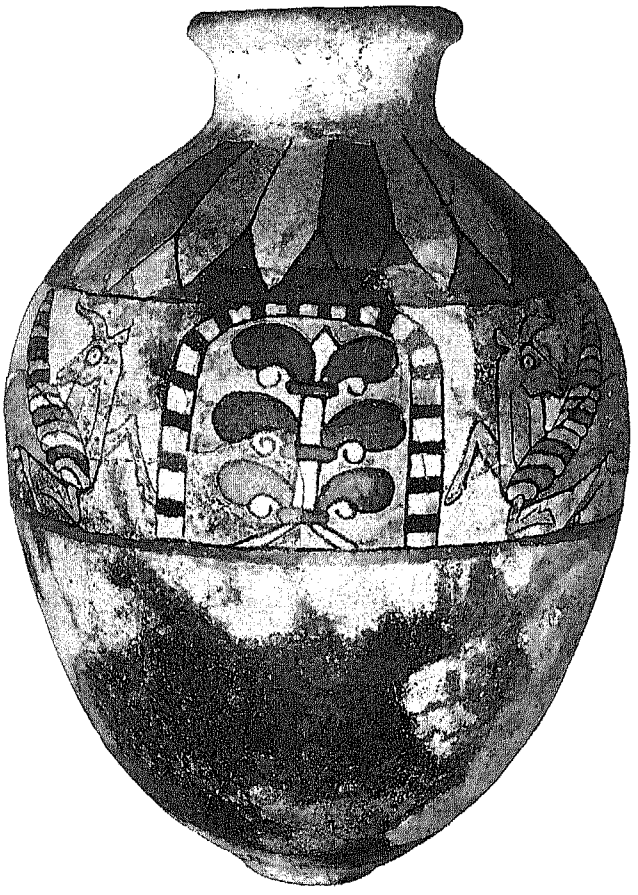
During the fourteenth–thirteenth centuries BCE, mosaic and marbled glass, which facilitated the incorporation of human, animal, and plant motifs, became popular in Mesopotamia. Stylistic considerations indicate the existence of independent glass-vessel production in northern Syria and perhaps on Cyprus, but Canaan made do with Egyptian imports. As in the rest of western Asia, glass vessels are mostly associated with palaces, temples, and the graves of the wealthy. They were used to hold costly liquids. Glassmakers fashioned a wide variety of opaque, colorful objects. The properties of glass, unlike those of faience (which remained essentially an imitative industry), were worked in the hot state and led to the production of highly distinctive vessels.

As with other industries, the continuity of glass production was beset by the problem of scarcity of material from the twelfth to the ninth centuries BCE. Crude tenth-century BCE glass vessels indicate a desultory continuity in Egypt. Compositional details of products from a factory at Frattesina in Italy suggests that some Near Eastern glassworkers may have been dispersed there in the collapse of Bronze Age palatial society. When vessel making revived in the eighth century BCE, rather mediocre core- and rod-formed examples are complemented by an important innovation: cast and cut translucent glass. These predecessors of clear blown glass were fit for royalty (examples are an alabastron from the North West Palace at Nimrud with an inscription of Sargon and a petaled bowl from a royal tomb at Gordion in Turkey). Phoenician glassworkers imitating crystal were probably responsible for the development, but they may have accomplished it in Assyria, where so many examples have been found, rather than in Phoenicia itself. By the seventh century BCE, both types of glass production were carried out in the Mediterranean region.

Glazed Pottery. The difficulty in effectively binding existing alkaline glazes to ceramic bodies was overcome in northern Syria and northern Mesopotamia during the sixteenth century BCE, as part of the same pyrotechnological revolution that brought about working glass industries. Glazers and glassworkers produced identical bottle shapes for northern Mesopotamian patrons, but glazers were restricted to monochrome blue. A derivative monochrome glazed-vessel industry was established in fourteenth—thirteenth-century BCE coastal northern Syria. Egypt did not produce glazed pottery in the Bronze and Iron Ages.

By the fourteenth century BCE, Mesopotamian glazers took steps to realize a major potential of glazed pottery: architectural decoration. At the provincial site of Nuzi, numerous glazed wall knobs were fixed to the walls of the Ishtar Temple. Glazers were employed for similar works on a monumental scale in Elam, and less so in Babylonia.

Once glazers prevented different colors from mixing on pottery bodies, they could produce bricks with polychrome



VITREOUS MATERIALS: Bronze and Iron Ages. *Polychrome glazed pottery jar.* In Neo-Assyrian style. From Ziwiye, c. 800 BCE, height 13.5 inches. (The Metropolitan Museum of Art, Harris Brisbane Dick Fund, 1951 [51.29.1])

designs on a monumental scale. This was achieved in Assyria at the end of the second millennium or in the ninth century BCE by installing slender ribs between the colors, a variation on goldworkers' cloisonné techniques. From the time of Ashurnasirpal II, Assyrian palace, temple, and fort facades were embellished with shimmering geometric and representational designs. It was a development destined to have many successors, from Neo-Babylonian to Islamic times.

Assyrian glazers applied the same polychromy techniques to pottery vessels by the ninth century BCE. In metropolitan Assyria, standardized polychrome bottles appeared commonly in tombs. A derivative industry prospered in northwestern Iran, while others began in Elam and Babylonia. In the late eighth century BCE, another center of production started in northern Syria, but its products are technically and stylistically related to the Babylonian industry, perhaps as a result of Assyrian deportations of Babylonian craftsmen. The importance of the center in northern Syrian is that it led to the foundation of secondary industries in the Mediterranean region. After the sixth century BCE, polychromy declined and utilitarian monochrome production became the norm.

EDGAR PELTENBURG

Artifacts of the Persian through Roman Periods

Before the invention of glassblowing in the first century BCE, vitreous artifacts were produced by the labor- and energy-intensive techniques of cast molding, rod forming, and core forming. As a consequence, glass in the pre-Roman periods was limited to a restricted number of forms: simple beads, furniture inlays, and luxury vessels used for cosmetics and in the dining room. The glassblowing and mold-blowing techniques developed during the Roman period, however, allowed glass to become as inexpensive and ubiquitous a commodity as it is today.

At the end of the Late Bronze Age (c. 1600–1100 BCE) there appears to have been a rapid decline in the production of glass artifacts in Egypt and western Asia (Barag, 1985). Although it seems from the dearth of evidence that few, if any, glass vessels were made in the early first millennium BCE, the appearance of glass beads in tenth- and ninth-century BCE contexts suggests that the art of glassworking did not entirely disappear in the Early Iron Age. Neo-Assyrian texts that record glass recipes have antecedents in second-millennium BCE Middle Babylonian and Hittite texts (Oppenheim et al., 1970). Two unusual mosaic glass beakers with figural decoration from a late ninth-century BCE level at Hasanlu may represent heirlooms from the thirteenth century BCE. In Egypt, the New Kingdom tradition of using cast, opaque glass in inlays seems to have revived in the Saite period, though the production of core-formed vessels stopped after the twenty-first dynasty (Grose, 1989). Cast monochrome and mosaic glass inlays for ivory and wooden furniture were produced by Phoenician craftsmen in the ninth and eighth centuries BCE, preserved examples of which have been found at Nimrud, Arslan Tash, Megiddo, and Samaria.

Glass vessels were once again produced in some numbers in Mesopotamia during the eighth and seventh centuries

VITREOUS MATERIALS: Persian through Roman Periods. *Western Asiatic unguent bottle (alabastron) probably from Mesopotamia.* Late eighth or seventh century BCE. Height 8.6 cm. BCE. Mesopotamian-produced core-formed glass alabastra and juglets have been found in Assyria, Bablyonia, Elam, Urartu, and Palestine, as well as in eastern and central Mediterranean contexts of the eighth and seventh centuries BCE (Barag, 1985). In addition to reviving the earlier techniques of core forming, glassworkers of this period discovered how to create monochrome glass in shades ranging from natural light green to intentionally decolorized or, more rarely, purple, blue, and blue-green. Monochrome cast-and-ground glass bowls and other vessels were found in great numbers in eighth- and seventh-century BCE contexts at Nimrud, including a thick vase inscribed with the name of Sargon II, and are also known from Khorsabad and Kuyunjik (Barag, 1985). An unusual late eighth-century BCE cast-and-ground mesomphalos phiale (shallow drinking vessel) from tumulus P at Gordion probably belongs to the same tradition (Grose, 1989). Stylistic similarities with Phoenician metal and ivory objects and the presence of cast monochrome vessels from early seventh-century BCE contexts on Crete and in Italy suggest that the discovery of this type of glass may well have been made by Phoenician artisans. [*See* Phoenicians.] By the seventh century BCE, Phoenician glassworkers were producing inlays of transparent painted glass and monochrome glass beads. By the sixth century BCE, glass technology had spread from the Near East and had become established at Greek, Punic, and Etruscan centers.

Persian Period. There is some limited evidence that the production of cast monochrome and core-formed vessels continued in the Neo-Babylonian and Early Achaemenid periods, though not on the same scale as in the previous eighth and seventh centuries (Moorey, 1994). During the Late Achaemenid period, a different type of cast monochrome vessel was produced in a lost-wax technique that employed a high-quality, intentionally decolorized glass particularly resistant to weathering. The earliest dated example of an Achaemenid cast monochrome vessel was found in a Cyrenaican tomb with Attic pottery from the third quarter of the fifth century BCE (Michael Vickers, "An Achaemenid Glass Bowl in a Dated Context," *Journal of Glass Studies* 14 [1972]: 15–16). In Aristophanes' *Acharnians* (ll. 73–75), first produced in 425 BCE, an Athenian ambassador returning from Persepolis boasts of having drunk from luxurious Persian gold and glass vessels, indicating the high esteem in which Achaemenid glass was held in antiquity. A related, but distinct, group of Achaemenid cast monochrome glass bowls has been found in fourth-century BCE contexts at Persepolis and at Ephesus (Oliver, 1970). The glass decorative elements used by some Greek sculptors and architects seem to have been made from raw monochrome glass imported from the Near East.

The production of core-formed vessels in Mesopotamia may have died out at the end of the sixth century BCE, when glass perfume containers made in East Greece began to be imported into the Near East (Grose, 1989). Greek core-formed glass alabaster, aryballoi, amphoriskoi, and oenochoae have been found in Syria, Jordan, and Israel in contexts ranging from the late sixth century BCE through the Hellenistic period. A related series of tall, narrow kohl tubes, formed on a rod without a core, were produced in both the eastern Mediterranean and the Near East during the sixth–fourth centuries BCE. [*See* Cosmetics.] Workshops active in northwest Iran and in Mesopotamia during the late fifth and fourth centuries BCE seem to have been responsible for two groups of rod-formed kohl tubes that are square in section and made of a dark translucent glass decorated with opaque glass threads combed into tight zigzag designs (Barag, 1975; Grose, 1989).

The rod-forming technique had been used to make colored glass beads in Mediterranean and Near Eastern workshops from at least as early as the ninth century BCE. Rod-formed polychrome opaque glass beads and pendants in the shape of human or demonic heads and animals have been found in large quantities in Syro-Palestinian, eastern Mediterranean, and Punic contexts from the early sixth–the third centuries BCE. [*See* Jewelry.] While the origin of these beads has been variously ascribed to Phoenician, Punic, or East Greek centers, it is likely that they were produced in a number of different workshops over a period of several centuries (Barag, 1985). Monochrome glass was also extensively used to produce seals and scarabs in the Persian Empire, and examples have been found at sites from Cyprus to Mesopotamia. [*See* Seals.]

Hellenistic Period. The evidence indicates a sharp decline in the production of luxury glass vessels in the Near East during the century following the Macedonian conquest of the Achaemenid Empire. Achaemenid-style cast bowls may have continued to be produced in eastern Mediterranean workshops into the third century BCE, but the East Greek core-formed industry probably died out by 300 BCE. Few products from the new glass houses established in Italy and elsewhere in the Mediterranean in the third century BCE have been found in the Near East. One notable exception is a fragment of a gold-glass pyxis lid recovered in Babylon (Barag, 1985).

The second century BCE witnessed a dramatic renaissance in Near Eastern glass production. Monochrome, colorless, and intentionally colorized hemispherical bowls with simple molded or pinched ribs or with lathe-cut grooves around the rim were manufactured in large numbers at several different centers, including some located along the Phoenician coast, perhaps at Sidon. These hemispherical bowls were made with a simplified molding technique that involved sagging a heated disc over a convex mold. Hundreds of examples of hemispherical bowls have been found at sites on Cyprus and in Israel, and more than six thousand have been recovered from the small settlement at Tel Anafa (Israel) in levels dated to between 125 and 80 BCE (Grose, 1989). Simple plano-convex gaming pieces made out of the same type of monochrome glass have been found throughout the Near

VITREOUS MATERIALS: Persian through Roman Periods. *Eastern Mediterranean footed bowl (krater) possibly from Egypt, but reported to have been found in Italy.* Mid-late third century BCE. East and the Mediterranean, including a deposit of thirty thousand from the temple of Eshmun near Sidon (Maurice Dunand, "Verroteries d'enfants dans le temple d'Echmoun à Sidon," *Bulletin du Musée de Beyrouth* 30 [1977]: 47–50). [*See* Games.]

By the end of the third century BCE, glassworkers had rediscovered how to manipulate preformed canes or cane sections to produce a wide variety of polychrome mosaic glass vessels. It has been proposed that this discovery was made in Alexandria, where Egyptian glass artisans had a long tradition of working with glass canes. However, the distribution of the earliest examples of mosaic glass vessels suggests that they are products of southern Italian centers. In any case, mosaic glass vessels have been discovered at a number of Anatolian, Cypriot, and Near Eastern sites, including Nimrud, where Austen Henry Layard recovered a mosaic network-pattern bowl.

Core-formed vessels reappear in the Syro-Palestinian region in the late second and first centuries BCE. These Late Hellenistic core-formed types are easily distinguished from the earlier Mediterranean examples by shape and fabric. Piriform alabaster and globular amphoriskoi with looped handles of transparent glass are especially common on Cyprus and the Syro-Palestinian coast, where they were presumably made.

Roman Period. The most momentous development in the history of glassmaking—the invention of glassblowing—seems to have been made on the southern Levantine coast in about the middle of the first century BCE. Finds of glass tubes, partially blown bulbs, and wasters from a pre-40 BCE deposit in Jerusalem suggest that the first steps toward glassblowing involved the inflation of heated, preformed glass tubes (Yael Israeli, "The Invention of Blowing," in Newby and Painter, 1991, pp. 46–55). Glass artisans soon realized the advantages of using a metal blowpipe to manipulate heated globs of glass, and by the end of the first century BCE the art of glassblowing had spread to many centers throughout the Roman Empire.

During the first four centuries of the common era, workshops from western Europe to Mesopotamia took advantage of the glassblower's ability to fashion quickly and inexpensively a wide variety of utilitarian vessel shapes; glass became as commonplace, and probably as inexpensive, a commodity as ceramics. Assemblages of Roman glass display a remarkable consistency throughout this vast region, no doubt reflecting a high degree of interaction among Roman-period glass houses. Nearly every excavated Roman site has yielded glass dishes, plates, bowls, beakers, drinking cups, flasks, and perfume containers as well as glass bracelets, beads, gaming pieces, bezels, and other objects. Because individual glass workshops probably used glass from a number of different sources, including primary producing centers and recycled glass, attempts to define chemically regional groups most likely will continue to be inconclusive. Nonetheless, given the intrinsic difficulties of transporting fragile glass vessels, it can be assumed that most Roman sites were largely supplied by local glass workshops. Detailed studies of some glass corpora, such as those from Cyprus, Karanis, and Dura-Europos, have isolated some regional traits—Cypriot painted beaker lids, tooled pad bases characteristic of Egyptian products, and crude imitations of Syro-Palestinian forms at Mesopotamian sites. Literary and epigraphic references attest to the vitality of Egyptian, Phoenician, and Jewish glass workshops.

The proliferation of inexpensive blown glass did not, however, result in an immediate cessation in the production of handmade luxury wares. The mosaic glass tradition survived to the middle of the first century CE and cast monochrome ribbed bowls continued to be produced until the end of that century. In the second quarter of the first century CE, glass artisans discovered how to create decorated vessels by blowing glass into multipieced molds. It has long been assumed that the mold-blowing technique was developed at Sidon, though recently Italy has been suggested as a place of origin (Grose, 1989). From the third quarter of the first century through the fourth century CE, workshops throughout Europe and the eastern Mediterranean mass produced mold-blown vessels decorated with a wide variety of vegetal and figural scenes. During the same period, both eastern and western glass workshops produced colorless blown vessels decorated with wheel-cut designs, some of the finest of which are masterpieces of the intaglio technique.

There was no sharp change in the patterns of glass manufacture or use after the establishment of Constantinople in 330 CE. The basic categories of Late Roman glass types continued into the seventh century CE, when, with the rise of

MURRAY C. MCCLELLAN

Artifacts of the Byzantine and Islamic Periods

Glass was a ubiquitous commodity in the Near East during the Byzantine and Islamic periods. It was fashioned into utilitarian vessels, windowpanes, and inexpensive jewelry. It also was used to create luxurious mosaic decorations and ritual vessels for churches, synagoges, and mosques. In Late Antiquity, as today, glass was a part of the lives of the rich and the poor alike.

Byzantine Glass. From the fourth to mid-seventh century CE, the glass industry differed little from that in the preceding three hundred years. Since the invention of glass-blowing in the first century BCE and the development of the mold-blown technique in the following century, glass artisans had been able to make large numbers of vessels both quickly and inexpensively. Because it was relatively easy to manufacture glass objects but difficult to transport them, glass workshops were likely to be established near urban centers throughout the Byzantine Empire.

There were two distinct stages in the ancient glass industry: the initial production of raw glass, or cullet, and its subsequent crushing, refiring, and shaping. This two-step process was necessary because ancient kilns could not reach temperatures sufficiently high to fuse the basic soda-lime-silica components of ancient glass in a single firing. While it is probable that some glass factories undertook both activities, it is clear that there were centers dedicated to the large-scale manufacture of raw glass for sale to smaller workshops. These centers were no doubt located close to sources of good sands, such as the deposits at the mouth of the Belus River (the Na'aman River, north of Haifa), as well as in areas where an ample supply of wood for charcoal could be obtained. At one such center in Israel, Beth-She'arim, on the Kishon River, an 9.7-metric-ton (8.8-ton) slab of devitrified glass was uncovered in a fourth-century CE context (Brill, 1967). Because the poorly fused Beth-She'arim slab was unusable, it had been abandoned. A similar large slab, now in the Museum ha-Aretz in Tel Aviv was found at Rishpon, north of that city, on Israel's Mediterranean coast (Weinberg, 1988). That these large slabs were intended to be broken up and taken to smaller workshops is suggested by a third-century CE reference in the Babylonian Talmud (*Shab.* 154b) that mentions the transport of glass lumps on donkeys.

Glass cullet from Beth-She'arim may have been sent to a glass workshop located a few kilometers to the east, at Jalame. The Jalame glass factory, dated by its excavators to 351–383 CE, was situated in an isolated complex that had been a functioning agricultural villa earlier in the century (Weinberg, 1988). The Jalame complex, the only early Byzantine glass-manufacturing factory excavated to date, included a furnace room, a glass-sorting area, and a massive dump of broken glass. No ceramic crucible fragments were found at the site, and it appears that the glassworkers at Jalame used small, rectangular limestone crucibles that would have been used for only a single melting of a relatively small amount of glass. Large numbers of broken vessels, manufacturing waste, and fragments of cullet were uncovered in the sorting and dump area to the south and west of the furnace, indicating that at Jalame, at least, little or no care was taken to save broken glass for reuse.

The wide range of utilitarian vessels produced at Jalame include the most typical shapes in use during the early Byzantine period: bowls, cups, jugs, bottles, jars, and conical beakers with sharp rims formed by cracking the vessel off from the blowpipe; the latter could have served as either drinking vessels or as lamps. These early Byzantine vessels tended to be decorated only minimally. Some jugs, bottles, and jars have simple mold-blown or pattern-blown ribbing, whereas tall flasks frequently were adorned with added trails. Conical beakers and bowls could be decorated with applied dots of a dark-blue glass. Rarely, simple designs were cut with a wheel on bottles and bowls.

In addition to these vessels types, windowpanes, bracelets, glass weights and stamps, and tesserae cut for mosaics were produced in the early Byzantine period. Windowpanes, which were either flat or crowned, tended to be made from a deeply tinted greenish or bluish glass that would not have admitted a great deal of light. Bracelets were frequently made of a very dark blue or green translucent glass and were occasionally decorated with tooling. Tesserae for mosaics, usually cut from thin cast slabs, appear in a range of colors, including some with thin gold foil sandwiched between colorless glass. Some small glass disks with stamped inscriptions were used as weights, while others seem to have been used as tokens. In contrast to glass vessels, the more portable bracelets, tesserae, and weights and tokens were often traded great distances from their place of manufacture.

In the Late Byzantine period, the proliferation of new churches and synagogues stimulated the glass industry. In addition to windowpanes and glass tesserae, lamps and goblets for liturgical uses were often supplied by glass workshops, which thrived (van Saldern, 1980). The period also saw the production of elaborately decorated vessels, such as the engraved chalice found in the cathedral at Jerash, or the group of late sixth–early seventh century CE mold-blown hexagonal bottles with Christian and Jewish religious symbols (Barag, 1970, 1971). Quantities of three-handled hanging lamps and stemmed lamps for polycandela have been discovered in synagogues at Beth-Shean in Israel and Sardis in Anatolia and in churches at el-Lejjun, Khirbet al-Kerak, Jerash, and Pella in Jordan, at Samaria in Israel, and elsewhere (Meyer, 1988). Stemmed glass vessels, which, during the sixth century CE replaced the conical beaker as the dominant form used for lamps and drinking vessels, are also frequently found in settlement contexts, such as at Caesarea in Israel, where a hoard was recently discovered near the Byzantine city wall (Michael Peleg and Ronny Reich, "The

VITREOUS MATERIALS: Byzantine and Islamic Periods. *Palestinian hexagonal jar with Jewish symbols, probably made near Jerusalem.* Dated around 578–629 CE. Height 8.0 cm. (Courtesy The Toledo Museum of Art, purchased with funds from the Libbey Endowment, gift of Edward Drummond Libbey, 1923.1358)

Byzantine City Wall of Caesarea Maritima," *'Atiqot,* Eng. ser., 21 [1992], p. 155).

While the Jewish glass industry is particularly well documented in the textual and archaeological record, it is apparent that glass workshops were located throughout the Late Roman Empire. Even Cyprus, an island with no natural silicon sands, seems to have had a thriving glass industry in the Byzantine period, apparently supplied with raw cullet shipped from the mainland. Glass factories no doubt played an important role in their regional economies, though the location of the Jalame workshop and references to laws prohibiting the establishment of glassworks within city walls suggest that glass artisans did not fully participate in the *urbanitas* of the empire.

Islamic Glass. The Arab conquest of the Byzantine provinces of Syria and Egypt in the seventh century CE initially brought little change to the production of glass in the Near East. Glass workshops under the early Umayyad dynasty continued to produce simple flasks, lamps, and goblets of light greenish or bluish transparent glass. With the rise of the 'Abbasid caliphate in the eight century CE, however, Islamic glassworkers encountered the rich tradition of the Sasanian glass industry, which specialized in elaborate wheel-cut, faceted bottles, bowls, and ewers. While glass production in the remnants of the Byzantine Empire stagnated in the last two centuries of the millennium, Islamic glass production underwent a renaissance. Mesopotamian and Persian glass from the eighth and ninth centuries CE includes such luxury vessels as square bottles with faceted designs, elegant ewers with wheel-cut patterns of running animals and stylized flowers, and short flasks with mold-blown and relief-cut designs. Finds from Samarra on the Tigris River and Antioch in Syria testify to the reemergence at this time of the mosaic, or millefiori, technique, in which cane sections of colored, opaque rods are fused to form open bowls and plaques (Pinder-Wilson, 1991).

A major glass center developed at Fustat (Old Cairo) in the eighth century CE that produced glass for more than two hundred years. As the excavation of this area has revealed, quantities of simple blown vessels as well as more luxurious wheel-cut pieces were produced (Pinder-Wilson and Scanlon, 1973). Most early Islamic glass was composed of colorless or slightly tinted fabrics; however, intentionally colored glass was also used, such as the opaque blue-green glass of the engraved bowl, likely a product of Fustat, in the Treasury of San Marco in Venice. Syrian and Egyptian glassworkers in the eighth century CE were also responsible

VITREOUS MATERIALS: Byzantine and Islamic Periods. *Bottle with wheel-cut ornament, probably Iranian.* Ninth–tenth century. Height 15.0 cm. (Courtesy The Toledo Museum of Art, purchased with funds from the Libbey Endowment, gift of Edward Drummond Libbey, 1947.5)

for developing two new decorative techniques: applying stamped designs and inscriptions using carved metal tongs, and lustre painting. The latter technique, in which metal oxides are applied to a vessel with sulphur and vinegar and fired in a reducing kiln, was used to produce vessels with elaborate polychrome Kufic inscriptions, such as one from Fustat that was dedicated to the governor of Egypt in 772 CE (Pinder-Wilson, 1991).

A spectacular collection of Fatimid glass has been recovered from a ship wreck off the coast of Turkey, near Serçe Limanı, in about 1036 CE (Bass, 1984). [*See* Serçe Limanı.] In addition to a cargo of ceramic cooking vessels, Byzantine transport amphoras, intact glass vessels, arsenic ore, and raisins, the ship was carrying a ballast of nearly three tons of glass cullet. Two-thirds of this ballast was in the form of broken chunks of raw cullet; the remainder was composed of approximately one million glass fragments. It is estimated that the fragments represent the remains of some ten thousand to twenty thousand vessels, in addition to waste-glass trails and glass pads cracked off from pontils. More than two hundred vessel types have been identified, including beakers, handleless and one-handled cups, dishes, bowls, jugs, bottles, flasks, jars, and lamps. A large number of these vessels were decorated with mold-blown and pattern-blown designs, including diamond, honeycomb, and vegetal patterns, or with wheel-cut designs of geometric, floral, and animal motifs. The Serçe Limanı ship, evidently plying the waters between Fatimid Syria and the Byzantine coast during a period of quietude after the peace treaty of 1027 CE, was clearly supplying a number of small glass workshops with raw material; the evidence suggests that, in the Mediterranean at least, there was little long-distance trade for finished glass vessels.

The Seljuk conquests and the collapse of the Fatimid dynasty in 1171 severely disrupted the established Islamic glass industry. It has been hypothesized that glassworkers fleeing Cairo set up a new production center in Corinth, Greece, during the late twelfth century, although a recent redating of the Corinthian material suggests that the glassworks there may date to after the Norman conquest in the early thirteenth century. In any case, it is clear that the late twelfth century was a period of cross-fertilization between Islamic and European glass-manufacturing traditions. The so-called Hedwig glasses, bucket-shaped vessels decorated with elaborate relief-cut heraldic lions, griffins, and eagles, may have been made by Islamic workers in Norman Sicily and traded to northern Europe (Pinder-Wilson, 1991). A class of tall, dark-blue translucent bottles found in Greece and on Cyprus was decorated with enamel and gold-paint techniques apparently developed in Egypt and Syria. Conversely, the Western tradition of prunted, or fused, decoration appears on Islamic glass in the early thirteenth century.

During the thirteenth century, the cities of Aleppo and Damascus in Syria were renowned as major centers of glass production. Both produced elaborate enameled vessels, although it is not clear whether the stylistic differences traditionally attributed to each center are valid. Also during this century, tall sprinkler bottles and small flasks with multicolored marvered decoration became popular. Vessels of these types have been uncovered at the thirteenth- and fourteenth-century Red Sea port of Quseir el-Qadim and have been interpreted by their excavators as export goods destined for India and east Africa (Whitcomb, 1982). In the fourteenth century, the Syrian centers produced a series of magnificent enameled hanging lamps, often with painted inscriptions recording the commissioning of the lamp, that were distributed throughout the Mamluk territories.

VITREOUS MATERIALS: Byzantine and Islamic Periods. *Flagon, probably Syrian.* Dated to about 1300 CE. Height 13.6 cm. (Courtesy The Toledo Museum of Art, purchased with funds from the Libbey Endowment, gift of Edward Drummond Libbey, 1927.317)

It is unlikely that the Aleppo glass industry survived the Mongol sack of 1260, whereas the Damascus workshops continued until their workers were carried off by Tamerlane's troops to Samarkand in 1400, ending a long tradition of glassworking. After this event, luxury glass vessels used in the Mamluk sultanate were supplied by Venetians or Persians.

MURRAY C. MCCLELLAN

VOGÜÉ, MELCHIOR DE (1829–1916), French Orientalist, first a count and then a marquis, born to a very old family of the Vivarais (central France) and educated in Paris. Following a diplomatic internship, de Vogüé became attracted to Oriental studies. His first trip to the Near East, in 1853, resulted in his first book *Les églises de la Terre Sainte* (Paris, 1860). In 1860–1861, he explored Palmyra and the Hauran. Early in 1862, with the epigraphist W. Waddington and the architect E. Duthoit, Vogüé made a brief but important survey of Cyprus (in the place of Ernest Renan) and then returned to Syria. A second book appeared in 1864, *Le Temple de Jérusalem*. His most important work, *Syrie centrale*, in two volumes (Paris, 1865–1877) included a study of the region's architecture; a third volume (in two parts, 1868–1877) reported on Aramean and Sabean inscriptions, for by then de Vogüé had mastered Semitic epigraphy.

After the 1870–1871 Franco-Prussian War, Vogüé again served as a diplomat, as ambassador to Constantinople (beginning in 1871) and to Vienna (beginning in 1875). After Renan's death (1892), de Vogüé became president of the commission for the *Corpus Inscriptionum Semiticarum (CIS)* at the French Académie des Inscriptions et Belles-Lettres (of which he had become a member in 1868). De Vogüé was in charge of volume 2 of the *CIS*, for Aramean inscriptions (1889–1907). A member of many learned societies, he was greatly renowned for his mastery of several fields in Oriental studies, especially those dealing with archaeology, inscriptions, and ancient coins. Some of his numerous articles were republished in *Mélanges d'archéologie orientale* (Paris, 1868) and in 1909 he received, in Paris, as a tribute, the book *Florilegium, ou Recueil de travaux d'érudition dédiés à Mr le marquis Melchior de Vogüé*. The marquis was an impressive figure in terms of science and in probity.

OLIVIER MASSON

VOUNI, site of the only excavated classical palace on Cyprus (35°09′ N, 32°47′ E). The Vouni complex was built on a promontory 268 m (879 ft.) above the sea, 6.5 km (4 mi.) southwest of Soloi, at the beginning of the fifth century BCE. The initial construction phase of the palace and its associated town was probably undertaken by a Cypriot king who needed headquarters for a garrison. The palace was essentially Near Eastern in plan (Müller, 1932; Maier, 1985), its main apartments were arranged around a colonnaded court, one side of which was reached by a monumental staircase. According to the Swedish Cyprus Expedition excavators (Gjerstad et al., 1937), the two building periods belonging

to this first phase of the palace are dated from about 500 to 450. There was a temenos complex associated with the palace of the first period. Deposits of votive sculptures were found along the staircase leading to the altar court of the temenos. Along the northeast side were ranged rows of limestone figures, and on the southwest side there were only terra-cotta statuettes. Similarly arranged but smaller groups of sculpture were found in other rooms of the temenos. The entire complex was defended by a massive fortification wall whose rampart was traced around the entire perimeter of the plateau atop the mountain, and then downward toward the sea, enclosing the settlement within.

The ruler of Vouni in the mid-fifth century rearranged the royal apartments. The "second" palace consisted of state apartments (with bathrooms) reached by a monumental staircase and large storerooms all constructed around two separate courtyards. The dates of this second phase are believed to be around 450–440 to about 380. A temple of Athena was built on the upper terrace of the plateau at the time of the reorganization of the palace. The platform on which the temple stands was cut into the limestone bedrock of the mountain; where there was a dip in the surface it was filled in with limestone chips. This is the same leveling technique used at the Lady sanctuary at Aradhippou and in the temenos of the Young Lord at Idalion.

The settlement area at Vouni extended down the slopes of the hill toward the sea, with roads traceable to Marion on the west via Limnitis and Soloi to the east. Between the settlement and the palace, on the northern slopes of the hill, between about 225 and 190 m (738–623 ft.) above sea level, rock-cut tombs contemporary with the second palace period were found. The entrances of these tombs gave directly onto the slope, making the use of a dromos unnecessary. All the tombs were emptied by the time modern excavators came to investigate.

Thus the town at Vouni was built in topographic zones. At the lowest level lay the houses, well built of cut stone. Above them was a strip of tombs, and above those was the palace surrounded by small chapels and secondary temenoi. At the top was the sanctuary of Athena. At the beginning of the fourth century the palace was destroyed by fire and not rebuilt, and the settlement went out of existence.

PAMELA GABER

VOUNOUS, Early Bronze Age site on Cyprus. Standing proud of the coastal plain that runs gently down to the sea from the steep north slopes of the Kyrenia range, Vounous, more accurately, Vounoi, is a hillock in northcentral Cyprus (35°18′54″ N, 33°22′26″ E). The top of the hill forms a small limestone plateau bounded to the south, east, and west by deep ravines leaving the naturally defined northern slope as a choice burial ground. The reasons for this decision were clearly determined by the soft, homogeneous, easily excavated quality of the rock and perhaps also the moderate incline, which ensured proper drainage. Bellapais, with its fine fourteenth-century abbey, is the nearest village, 2 km (1 mi.) to the southwest; hence the site's full name is Bellapais *Vounous*.

The presence of Early Bronze Age burial chambers in the area was first mentioned in 1926 by Einar Gjerstad, who called the site Kasafani *Keranienkomi*. Extensive looting in this locality was reported to the Department of Antiquities in 1931, and the ensuing excavation of thirty-one tombs that year and another seventeen the following was conducted by Porphyrios Dikaios, curator of the Cyprus Museum. These rock-cut tomb chambers, which are approached via an open-air passage *(dromos)*, were numbered consecutively 1–48 and subsequently published by Dikaios in 1940. The quantity, quality, and variety (shape and decoration) of pottery, as well as the copper-base tools, weapons, and ornaments accompanying the single or multiple burials were impressive. Anthropomorphic and zoomorphic figures applied to pots, in addition to clay models, provided valuable insight into the material culture and customs of the Early and Middle Bronze Age.

In 1933 Claude F.-A. Schaeffer, representing the National Museums of France, collaborated with Dikaios in the excavation of a further thirty tombs, numbered consecutively 49–79, which, apart from a preliminary report in 1936 by Schaeffer, remain unpublished. The final excavations at *Vounous* were sponsored by the British School of Archaeology at Athens and directed by James R. Stewart in 1937. He investigated a further eighty-four tombs, numbered consecutively 80–164, located in Cemeteries A and B, the latter previously dug by Dikaios and Schaeffer. Stewart's report

published in 1950, was followed in 1962 by a detailed analysis of all his finds from *Vounous*, classified according to the most complex typology ever devised for archaeological material. Since 1974 this seemingly inexhaustible burial ground has suffered from repeated bouts of looting.

To date the greatest number of excavated Cypriot Early Bronze Age tombs with the most varied ceramic assemblage comes from the *Vounous* cemetery. It has played a central, often controversial, and ambiguous role in any discussion dealing with the development of the period, a situation exacerbated by the absence of any excavations at the contemporary but elusive settlement(s) expected to exist in the vicinity. Nevertheless, the cultural material certainly belongs near the beginning of a vigorous artistic tradition that lasted seven hundred years, starting around 2400 BCE.

The economic basis for such a conspicuously wealthy community remains obscure. The site is not near copper mines or an obvious trade route for the export of metal and other products, yet the presence of several Levantine and Aegean objects suggests contacts beyond the island's shores.

W

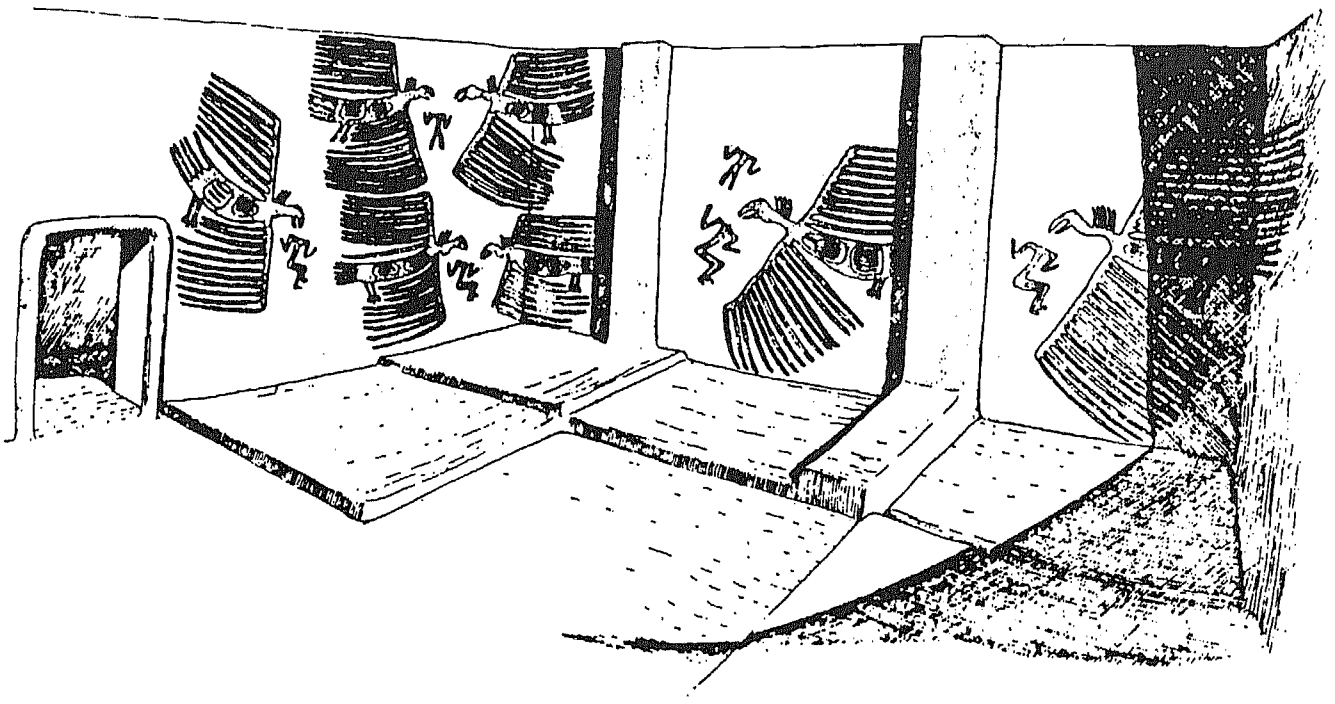
WADI _____. *For toponyms beginning with this element, see under latter part of name.*

WALL PAINTINGS. In the ancient Near East, wall painting was one of the most widespread and important artistic media. Although less able to withstand the ravages of time than other art forms, it is widely attested among the sedentary cultures of western Asia in many periods and contexts—as private domestic decoration, on official religious and palatial buildings, and eventually in tombs as well. Essentially as old as architecture itself, the popularity of wall painting depended not only on its inherent potential for rich, colorful effect on any scale, but also on the tractable and relatively inexpensive nature of the technique. Generally, the paint consisted of earthen pigments suspended in a water medium and applied to a dry plastered (mud, lime, or gypsum) surface. As such it could easily reproduce the scale and effect of other, more costly media, such as monumental relief or textiles.

During the Neolithic period (ninth–sixth millennia), wall painting emerged initially as monochrome embellishment at sites across the Levant, Anatolia, and Iran; it remained current in the Near East for millennia. The first polychrome wall paintings were simple zigzags patterns, although more elaborate geometric compositions evolved fairly rapidly in the later Neolithic in the centuries before and after 6000 BCE. The wall paintings from Çatal Höyük in Anatolia include multicolored compositions of triangles and lozenges organized as larger panels; they have been dubbed the Kilim style because of their similarity to the patterns in the woven rugs and wall hangings still produced in modern Turkey. By the early sixth millennium, the painters of Çatal Höyük had developed fairly complex figural compositions: hunting scenes, large birds of prey in flight above schematic headless humans (see figure 1), and the first known landscape, with a volcano. While the imagery of these paintings seems to have focused on the natural environment and the role of hunting in the protourban economy, their significance and the function of the buildings they decorated (possibly religious) remain uncertain. [*See* Çatal Höyük.] The wall paintings in the Late Neolithic houses at Tell Bouqras and Umm Dabaghiyeh in Syria suggest that the animal and geometric repertory at Çatal Höyük was current over a broader area of the Near East then. [*See* Bouqras.] In the ensuing Chalcolithic and Early Bronze Ages (fifth–fourth millennia), geometric ornament became the dominant mode of painted wall decoration in Anatolia, Iran, the Levant, and Syria (see figure 2). Notable exceptions are the mid-fourth-millennium enigmatic paintings from Teleilat el-Ghassul in Jordan: in one highly stylized, masklike human faces and animals grouped around a large starlike emblem and in others, a leaping tiger and a group of standing and seated human figures. [*See* Teleilat el-Ghassul.]

What is known of wall painting in Mesopotamia begins with Sumerian culture in the fourth millennium, primarily in the Protoliterate period (3500–3000 BCE), in which the development of monumental religious architecture stimulated the production of large-scale programs of wall painting. The Late Protoliterate temple at Tell ʿUqair continued the monochrome treatment and rectilinear ornament that had long been current in wall painting across western Asia. At ʿUqair, however, the geometric repertoire was enriched by files or pairs of human figures (divinities?) and animals that would soon come to typify Sumerian, or Mesopotamian, glyptic art and sculpture. The private domestic wall painting of this and later periods retained the simpler monochrome or geometric format. The wall painting of the succeeding Early Dynastic era, and indeed of the entire third millennium, is poorly documented. The only surviving examples are the fragments of bulls and human figures from the Temple of Inanna at Nippur, and the related imagery in the Temple of Ninḫursag at Mari (Tell Hariri). Because the architecture of the Akkadian period is virtually unknown, no wall paintings of this era have yet been discovered. Even the well-attested Neo-Sumerian monuments of the late third millennium have so far failed to produce any remains of wall painting.

The rich array of paintings from the Amorite palace at Mari (Tell Hariri), datable to the Old Babylonian period in the nineteenth or eighteenth century BCE, constitutes the earliest known Near Eastern program of painted decoration from a royal residence. The Mari paintings display various scenes of ceremonial (especially worship or presentation)



WALL PAINTINGS. Figure 1. *Paintings, room VII, Çatal Höyük.* (After J. Mellaart, "Excavations at Çatal Hüyük, 1963: Third Preliminary Report," *Anatolian Studies* 14 [1964]: 65, fig. 20)

imagery, asserting the ruler's privileged claim to divine guidance and support, along with images of abundant water and vegetation, symbolizing agricultural prosperity (see figure 3). Since they conform only generally to the iconographic traditions of earlier Akkadian or Sumerian and contemporary Old Babylonian sculpture, the Mari paintings help to form some notion of the corresponding Mesopotamian wall painting of the later third millennium. [*See* Mari.]

While the Mari paintings demonstrate the impact of Sumero-Babylonian art on the Semitic cultures at the periphery of Mesopotamia, the landscape in the wall paintings of the level VII palace at Alalakh (Tell ʿAṭchana, eighteenth century BCE), near the North Syrian coast, reflects the pictorial themes and sinuous dynamism of Minoan art. Also of Minoan inspiration are the painted imitations of stone wall orthostats and timber lacing in the level VII palace and the later second-millennium house 39/A of level IV at Alalakh, and in the palace at Qatna, somewhat farther south. [*See* Alalakh; Minoans.] The presence of Minoan ornamental motifs and fictive stonework in some of the Mari paintings also shows that the Syrian interior was not immune to such influence from the west at an early time. In the same way, the paintings of the Mitannian governor's palace at Nuzi betray the impact of Levantine traditions farther into Mesopotamia later, in the fifteenth century BCE. [*See* Nuzi.] There, the stylized, voluted sacred trees inserted amid a textilelike geometric polychrome framework reflect the fertility imagery of contemporary Syrian, or Canaanite, art; at the same time, the stylized bull heads and Hathor masks reflect the impact of Egypt on the Levant. The wall paintings of the Middle Assyrian king Tukulti-Ninurta I (1244–1208 BCE) at his palace in Kar-Tukulti-Ninurta (Tulul al-ʿAqir) near Aššur, adapt, in their turn, the sort of stylized trees and framework of the Nuzi paintings; they document further the assimilation of Levantine precedent that provided the basis for the sacred tree imagery of Neo-Assyrian art during the first millennium BCE. In contrast, the Late Kassite period paintings (twelfth century BCE) from the Babylonian palace at Dur Kurigalzu (ʿAqar Quf) represent a more local, Mesopotamian tradition; these consist of files of male figures, possibly officials, painted along the dados of deep doorways. Although the style is closely related to contemporary Kassite relief sculpture, the processional imagery also prefigures one of the major themes of later Assyrian and Persian art.

Wall painting continued to play a leading role in Near Eastern palatial decoration of the first millennium BCE. The finds from Nimrud (Kalah), Khorsabad, and Til Barsip indicate that such decoration was a standard feature of Neo-Assyrian palaces. The painting from residence K at Khorsabad (Dur Sharrukin, 722–705 BCE), where the king and an attendant reverently confront a standing deity, recalls the imagery of the Mari paintings a millennium earlier. The Assyrian taste for multiple, superimposed rows of stylized lotuses, palmettes, and other plants in the paintings from Khorsabad, Til Barsip, Nimrud, and Tell Sheikh Ḥamad also recalls the Middle Assyrian paintings of Tukulti-Nin-

urta I or those from Mitannian Nuzi. The extensive series of paintings from the provincial Assyrian palace at Til Barsip in Syria, datable to the ninth and eighth centuries BCE, closely parallels the kingly themes of court ceremony, military conquest, and hunting current in the monumental wall relief of Neo-Assyrian royal palaces (see figure 4). The Til Barsip paintings also provide important evidence for the polychromy of the corresponding wall reliefs that were originally painted. Above all, they suggest the significant role that monumental wall painting may have played in the development of such pictorial architectual relief in Near Eastern art of the first millennium BCE. The paintings at Tell Sheikh Ḥamad demonstrate the impact of palatial decoration on the houses of the wealthy elite. What is known of the painted embellishment of religious buildings at this time is unfortunately only fragmentary. [*See* Nimrud; Khorsabad; Til Barsip; Sheikh Ḥamad, Tell.]

In contrast to the rather slim and isolated evidence for the second millennium BCE in Anatolia, first-millennium BCE sites in the area are relatively rich in remains of wall paintings, especially to the east, in the Urartian kingdom of the Van region during the eighth and seventh centuries BCE. Despite their distinctive, local style, the paintings of divinities from the temple at Arin-Berd and the stylized floral frieze from the palace at Altintepe reveal the impact of Neo-Assyrian wall painting on that of Urartu. [*See* Urartu.] Egyptianizing features in the hunt scene from the palace at Arin-Berd, however, suggest connections with contemporary

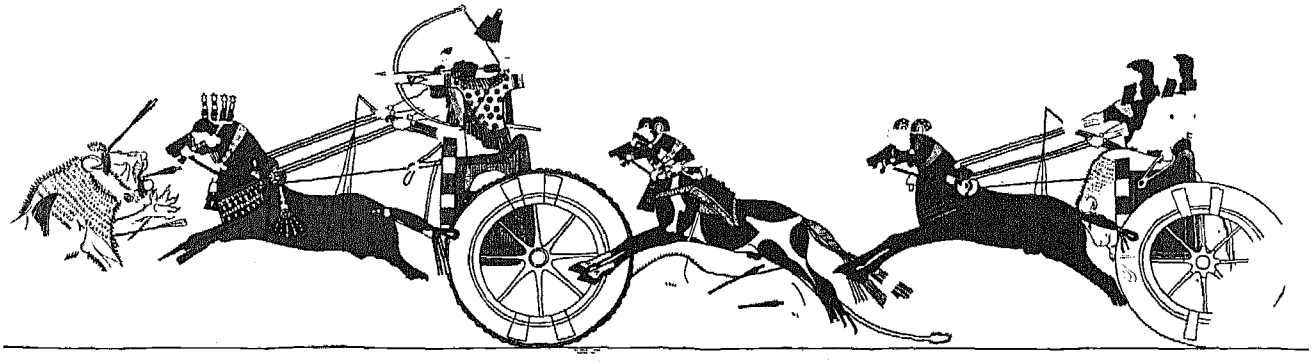
North Syrian, or Phoenician, art. A strong egyptianizing tendency is also evident in the fragmentary wall painting of a seated female figure at Ḥorvat Teiman in southern Israel, the only early first-millennium site in the Levant that has so far produced any wall painting. The style reflects not only proximity to Egypt, but the Egyptian orientation of the Canaanite and Phoenician art that exerted a formative impact on the art of the Israelite kingdom.

The first millennium BCE also witnessed a marked upswing in the currency of glazed ceramic brick and tile, which provided a more durable form of wall painting. Some were small-scale, with one or more figures or ornamental motives depicted per tile, but the technique could also be used for large-scale compositions consisting of many bricks. Eventually, the process was applied to brick relief sculpture as well. The Assyrians of the first millennium preferred the more painterly flat glazed tiles, but in Babylonia, and farther east, in neighboring Elam in southwest Iran, the flat variety was often used alongside polychrome glazed ceramic relief. The best-known monuments of this type are the monumental floral and animal compositions on the Ishtar Gate and the facade of the throne room at Babylon, constructed by Nebuchadrezzar II in the early sixth century BCE. In keeping with local Elamite tradition, the Persians of the Achaemenid period (559–332 BCE) retained the use of both flat and relief polychrome glazed brick. Decoration of this type figured especially prominently in the royal palace at Susa, the Persian capital, where the technique was used to depict the types of imagery executed in stone relief at the palace of Persepolis: figures of the king, composite animal guardians, and processions of soldiers and attendants. Remains of true wall painting, however, are exceedingly rare in Achaemenid Persia. Fragmentary remains from the palace of Artaxerxes II at Susa nevertheless indicate that like the Assyrians before them, the Persians too had an official tradition of wall painting that closely paralleled the themes and composition of contemporary architectural sculpture. The late sixth and early fifth-century BCE tomb paintings discovered in Lycia in Anatolia, at the western extreme of the Persian Empire, are essentially Greek in style or workmanship and local in function, although the ones at Karaburun depict Persian ritual and costume. [*See* Babylon; Lycia; Persepolis; Susa.]

The conquest of the Persian Empire by Alexander the Great (332–323 BCE) and the consequent imposition of Greek political, religious, and material cultural standards greatly altered artistic development in the Near East for centuries to come. The peoples of the more westerly and coastal regions of Anatolia had long before adopted the outward forms of Greek art, and during the Hellenistic period a similar situation developed under the Seleucid monarchy in much of Syria and the Levant. Even in Mesopotamia and Iran, which eventually shook off Greek political control with the advent of the new Iranian dynasty of the Parthians (171 BCE–249 CE), native Asiatic artistic traditions continued to coexist in fluid interaction with imported Greek conceptions. Although the evidence is fragmentary, wall painting figured prominently in the official buildings and wealthy villas of the Seleucid period. The remains of paintings from Aššur, the palace at Hatra, and central Asiatic sites such as Toprak-Kala and Kaltchayan demonstrate that the Parthians too made ample use of this medium. In the first- or second-century CE paintings at Kuh-i-Khwaja in eastern Iran, Greek themes and styles were mixed with poses and costume derived from central Asiatic art. Farther west, among the Semitic peoples at the frontier of the Roman Empire, the already synthetic Parthian artistic traditions interacted with Greco-Roman artistic concepts, a process perhaps best exemplified in the various wall paintings from the Roman caravan town of Dura-Europos. The votive paintings from the temples of Bel and Zeus Theos, and the temple of the Palmyrene gods, combine a strong emphasis on frontal pose, costume, and stylistic abstraction associated with Parthian art, alongside details of dress, military regalia, and winged victories of Greco-Roman derivation. A similar syncretism of Greco-Roman and hellenized Iranian artistic alternatives typifies the most famous of the Dura wall paintings—an extensive assortment of scenes from the Hebrew Bible produced for the synagogue shortly before the town was destroyed in 256 CE. These paintings constitute a rare exception to the ban on images customary for Jewish religious art, and they attest to the greater artistic flexibility that Jewish communities may have assumed in the mixed cultural environment of this region. Nevertheless, at times, the cultural balance could tilt decidedly: the New Testament imagery of the paintings from the Christian baptistery at Dura seem to relate more directly to Greco-Roman prototypes from the West, while the equestrian hunting and banqueting scenes in the mithraeum and house M7 reflect a more Parthian, or Iranian, taste. Farther west, in the wall paintings in the tomb at Tyre, the style, format, and mythological subject matter were entirely Roman. The winged victories and mythic subjects painted in the Tomb of the Three Brothers at Palmyra also attests to a more overtly Greco-Roman taste sometimes adopted among the local Syrian peoples. [*See* Dura-Europos; Palmyra; Parthians; Tyre.]

This situation continued to obtain down to the end of antiquity. Classical standards prevailed in the Roman or Early Byzantine provinces of Asia Minor and the Levant, but trailed off toward Mesopotamia and eastern Anatolia. Across the Euphrates River, under the rule of the Sasanian Persian dynasty that succeeded the Parthians (249–651 CE), a hellenized Iranian art remained broadly current across much of the Near East and was stimulated periodically by contacts with central Asiatic art, and even from the hellenized art of northern India. Sasanian wall painting has only rarely been preserved, but Roman literary sources attest to its importance in palatial decoration. [*See* Sasanians.] The third–fourth-century examples from Susa are still stylistically related to those from Kuh-i-Khwaja, just as they recall the Parthian hunting imagery of paintings at Dura-Europos. With the emergence of the Arab Empire and the end of Late Roman or Byzantine political authority in Syria and the Levant during the seventh century CE, the Asiatic transformation of Greco-Roman themes and styles also assumed a new momentum and vitality in the nascent art of Islam. Despite the Islamic ban, figural wall painting remained a significant medium for the secular sphere in wealthy private residences like the early Umayyad pleasure villas at Quṣayr



WALL PAINTINGS. Figure 4. *Painting, room 27, Assyrian palace, Til Barsip.* (After F. Thureau-Dangin and M. Durand, *Til-Barsib*, Bibliotheque Archéologique et Historique, vol. 23, 1956, pl. 530)

'Amra in Jordan and Qaṣr al-Ḥayr West in Syria. [*See* Quṣayr 'Amra; Qaṣr al-Ḥayr al-Gharbi.] The paintings adapted the courtly imagery and bathing scenes popular in Late Roman and Sasanian art. Such painting was still current in the ninth century 'Abbasid palace at Samarra in Iraq. However, it was in the domain of arabesque and geometric ornament, in the more durable medium of glazed tile, that the old Near Eastern tradition of wall painting found its fullest expression under Islam. [*See* Samaria, *article on* Islamic Period.]

WARFARE. *See* Weapons and Warfare.

WARREN, CHARLES (1840–1927), renowned excavator of Jerusalem's Temple Mount and southeastern hill (1867–1870). Most of General Sir Charles Warren's military service was spent in South Africa, where he took part in the relief of Ladysmith. He served briefly as chief commissioner of the London Metropolitan Police (1886–1888) and at the time of his retirement was colonel commandant of the British Royal Engineers (1905).

In 1867 Warren was commissioned by the Palestine Exploration Fund (PEF) to study the features of Jerusalem's historic structures. Although his excavations of the south and southeastern walls of the Old City have been dismissed by some (Roger Moorey, *A Century of Biblical Archaeology,* Cambridge, 1991) because they failed to resolve the area's formidable topographical questions, this is to ignore the wider significance of Warren's work. His investigations, which preceded the development of stratigraphic excavation, are still noteworthy because of the careful plans and diagrams he provided, achieved by exploring, under extraordinarily arduous and dangerous physical conditions, much of underground Jerusalem. These were published with the Jerusalem volume (London, 1884) he edited with Claude R. Conder.

By mapping rock contours, Warren was able to establish, for the first time, the relationship of the walls of the Haram esh-Sharif on the Temple Mount to the rock surface. He also examined the waterworks deriving from the Gihon Spring and was the first to go through the Siloam Tunnel on the city's southeastern hill.

Before leaving Palestine in 1870, Warren explored the southern part of the country and the area east of the Jordan River. His major publications include *Recovery of Jerusalem* (with Charles W. Wilson, London, 1871), *Underground Jerusalem* (London, 1876), and *The Temple and the Tomb* (London, 1880), in which he refuted the theories of the architectural writer James Fergusson (1808–1886), author of a contentious pamphlet on the Holy Sepulcher and other works about Jerusalem. Warren was distinguished as a Knight Grand Cross of St. Michael and St. George, a Knight Commander of Order of the Bath, and a fellow of the Royal Society. His involvement in Palestine continued for sixty years. He joined the committee of the PEF in 1871 and remained a member until his death.

YOLANDE HODSON

WAR SCROLL. One of several scrolls found in Cave 1 at Qumran, near the Dead Sea, the War Scroll (1QM) was acquired by the Hebrew University of Jerusalem and first published (posthumously) by Eliezer D. Sukenik in 1955; two rather small and inconsequential fragments appeared in Discoveries in the Judaean Desert (vol. 1, pp. 135–136). The fullest edition to date is that of Yigael Yadin, which includes an extensive introduction. It contains nineteen columns that describe a war sometimes defined as taking place between the "children of light" and the "children of darkness" (aided by the "Kittim") but sometimes between Israel and the Gentiles. This and other variations in language and ideology suggest a composite document, whose sources have nevertheless been organized in a fairly coherent way.

Column 1 summarizes the entire war, opening with a battle between the children of light and the children of darkness—the latter being nations living in Palestine or on its borders (the traditional biblical enemies of Israel—Edom, Moab, Ammon, and Philistia) and in league with the Kittim, who are present in Syria and Egypt and whose "domination" is thereby ended. Columns 2–9 deal in more detail with subsequent battles between the twelve tribes of Israel and the nations of the world (based on *Gn.* 10). They involve six-year campaigns interspersed with sabbatical years, making a total of forty years of combat, including the initial battle. Column 2 opens with the restoration of the Temple cult in Jerusalem (in the seventh year of the war, after the defeat of the Kittim?). Columns 3–9 describe the inscriptions on trumpets and banners, the lengths of banners, battle arrays and weaponry, the ages of participants, and, finally, military maneuvers. Columns 10–14 comprise a variegated collection of liturgical pieces. Columns 15–19 describe in detail a seven-stage battle between the children of light and the children of darkness, directed by priests, assisted by heavenly hosts, and finally won by direct divine intervention (probably the one also described in col. 1).

The scroll thus combines a nationalistic scheme of world conquest by Israel with a seven-stage dualistic confrontation between the forces of light and darkness. The balance between fantasy and reality is precarious: the dualistic battle proceeds as if minutely choreographed; the nationalistic sections (cols. 2–9) contain some realistic data, such as the use of guerrilla tactics and lightly armed troops. Its genre has recently been compared with Hellenistic and Roman military manuals. It is certainly not an apocalypse. Its descriptions of the weaponry and tactics led Yigael Yadin to posit an imperial Roman date for it—and certainly most scholars see the Kittim in 1QM as the Romans. The scroll might be seeking to converge both dualistic and nationalistic eschatological schemes in a struggle against Roman domination. The manuscript probably dates to the late first century BCE or the first half of the first century CE.

Fragments found in Cave 4 at Qumran contain material similar to 1QM, which has led to attempts to construct an "original" War Scroll or to see 4QM as an abbreviated edition. Given the evidence of the sources in 1QM, it may be more likely that a variety of materials was in circulation concerning a possible future war, an idea rooted perhaps in the independent army constituted under the Hasmoneans.

PHILIP R. DAVIES

WATER TUNNELS. In the arid climate of the ancient Near East, the need for water was always fundamental and its proximity dictated the location of early settlement sites. Eventually, surface waters along rivers and lakes were manipulated into complex irrigation systems, rainwater was husbanded in storage reservoirs and cisterns, and underground sources, marked by oases and springs, were tapped by wells.

Water sources for agrarian use—crop irrigation and animal husbandry—were normally on the outskirts of a settlement site. However, as large population centers developed, their walled defenses made external access not only inconvenient, but a fatal weakness when under siege. Access via closed tunnel systems became an adaptation to the need for an intramural water supply.

Since the late nineteenth century, archaeologists working in Palestine have identified and explored such systems, most notably at Jerusalem, Gibeon, Megiddo, Gezer, and Hazor. At the first three, the systems exploited natural springs located on the slopes of their lower tell. These springs were created by natural karst-forming processes: the migration of groundwater through joints and bedding planes dissolves

and forms channels in the limestone bedrock. Interruptions in the bedding planes at fault lines or erosion at valley locations produces exposures at which water flows freely or settles into pools, or catchments. The caves and pools at the Gihon Spring at the foot of Mt. Ophel in Jerusalem are classic expressions of this process.

The various initiatives taken to secure springs and to access their waters from within a city are best illustrated at Megiddo, where three historical stages are evident. The first, prior to the tenth century BCE, involved only protecting the spring chamber by covering it and constructing a stairway access that could be blocked and masked under siege. A more ambitious second stage, constructed during the reign of King Solomon in the tenth century BCE, included a camouflaged gallery running through and below the city wall, connected to a long, covered stairway that lead downslope to meet the earlier entry to the spring chamber. In the ninth century BCE, a third-stage adaptation was engineered: a wide shaft, 35 m (115 ft.) deep, was sunk inside the city; from its base, a lateral tunnel 61 m (200 ft.) long was hewn to the spring chamber. The tunnel was pitched slightly downward, so that the water from the spring flowed to a storage sump at the base of the shaft. Water could be drawn from there by descending a long staircase that spiraled down the outer walls of the shaft opening.

A slightly earlier (twelfth century BCE) example of the second-stage, covered-stairway type is found at Tell es-Sa'idiyeh (biblical Zarethan), and intramural shafts and tunnels similar to the Megiddo stage-three constructions are found at Gezer and Hazor. However, at the latter two sites, the systems lead to internal subterranean pools, not to external springs. Their builders tapped waters deep in bedrock, a significant innovation. The ambitious scale of these shaft-and-tunnel excavations suggests that the engineers did not proceed by chance. A key to their confidence in finding subterranean water may be seen at Gibeon (Ar., el-Jib).

Gibeon's systems offer additional parallels to each of the three Megiddo stages, but with a significant difference in the third stage. Although, as at Megiddo, a tunnel was cut from the spring some 33.5 m (110 ft.) in the direction of the internal shaft, it ended some 4.6 m (15 ft.) away from the shaft base. The connection most likely was not completed because a feeding aquifer had already been tapped at the bottom of the shaft. If Gibeon's third-stage shaft system is indeed the "Pool of Gibeon" in *2 Samuel* 13–17, it would have been built before about 990 BCE and would thus be the earliest of the known and datable open-shaft/tunnel structures.

The most elaborate and complex of these early systems is on ancient Jerusalem's southeastern hill below the City of David. Its main elements were identified by explorers in the nineteenth century. In 1838 Edward Robinson discovered the 533 m (1,750 ft) long Siloam Tunnel (Hezekiah's Tunnel) that carries water from the Gihon Spring on the east to the Siloam Pool on the southwest; in 1867 Sir Charles Warren investigated a vertical shaft (Warren's Shaft) leading up from one of the lower spring and tunnel chambers to a more horizontal ramp tunnel that enters the city; and in 1886 Conrad Schick explored an irrigation tunnel in the bedrock (the Siloam Channel) that leads south from the spring and has windowlike openings all along the eastern ridge.

In the 1980s, the geological study carried out by Yigal Shiloh and his team showed that the development of each of these systems involved exploitation of natural karst features in the bedrock. Thus, the vertical shaft and the ramp tunnel above it were originally parts of a natural dissolution channel that was further shaped and expanded to provide access to the Gihon's waters from within the city walls. Based on its identification with the *ṣinnor* ("gutter" or "pipe") mentioned the story of David's conquest of the city in *2 Samuel* 5:6–10, early explorers referred to it as the Jebusite Shaft. It was accordingly dated pre-Davidic, before 1000 BCE. Although it is reasonable to assume that elements of the natural shaft and channel were present in David's time, the construction date for the more developed system cannot be ascertained on present evidence. However, the paleography of an inscription found in the Siloam Tunnel dates its construction securely to about 705 BCE, in the reign of Hezekiah. [*See* Siloam Tunnel Inscriptions.] Moreover, if the Siloam Channel is the "upper outlet of the waters of Gihon" that Hezekiah closed to direct waters west, as recorded in *2 Chronicles* 32:30, a *pro quem* date for the construction and use of that feature is also established.

JOE D. SEGER

WATZINGER, CARL (1877–1948), art historian and archaeologist, whose main research interest was in Greek art in the ancient Near East. Watzinger was born in Darmstadt, Germany. As a student he was awarded a fellowship (1901) to study at the German Institute in Athens. In 1903 the German Oriental Society commissioned him to publish wooden sarcophagi that had been excavated at Abu Sir in Egypt. The

product of his research was *Griechische Holzsarkophage aus der Zeit Alexanders des Grossen* (1905). He became a lecturer at Humbolt University in Berlin (1904–1905) and was a professor at the universities of Rostock (1906–1909), Giessen (1909–1916), and Tübingen (1916–1948).

Watzinger's archaeological work in the Near East began during World War I. He and Karl Wulzinger, the Byzantinist, worked with Theodor Wiegand, who had been appointed to lead extensive expeditions to Turkey, Syria, and Palestine. During this period, Watzinger worked at Jericho and Megiddo, two of the key sites in Palestine. The archaeological results of these expeditions were published as *Jericho: Die Ergebnisse der Ausgrabungen* (1913), by Ernst Sellin and Watzinger, and *Tell el-Mutesellim,* by Gottlieb Schumacher and Watzinger (1908–1929). Although excavation techniques were not fully developed at the time, the results of Watzinger's work were well published and remain useful research tools. Perhaps the best overview of Watzinger's many accomplishments in the fields of art history and archaeology appears in his biography of Wiegand (1944).

THOMAS A. HOLLAND

WAWIYAT, TELL EL-, site located in the Beth-Netofa Valley in Israel's Lower Galilee, some 12 km (7 mi.) north of Nazareth (map reference 178 × 244). The mound, one acre in diameter, rises above the valley floor to a maximum height of 3.75 m. The settlement's original name is unknown. On the basis of a biblical passage (*Jos.* 19:13–14), F.-M. Abel (*Géographie de la Palestine,* Chicago, 1938) suggested that the original name of Tell el-Wawiyat was Neah, a settlement within the territory of the tribe of Zebulon. Unfortunately, the modern name of the site (Ar., Tell el-Wawiyat; Heb., Tel Vavit), provides no assistance in securing this identification.

In 1986 and 1987 two seasons of excavation took place at the site under the direction of Beth Alpert Nakhai, J. P. Dessel, and Bonnie L. Wisthoff. The project was sponsored by the University of Arizona, in conjunction with the William F. Albright School of Archaeological Research in Jerusalem and the American Schools of Oriental Research. William G. Dever was archaeological adviser to the excavation. Thirteen 6 × 6 squares, revealing six strata of occupation, were excavated, twelve of them in the eastern sector of the tel. Archaeological remains dating to the Iron Age were found 20 cm below the surface.

Middle Bronze Age II–III. The earliest period uncovered at the site, discounting several sherds from the Chalcolithic and Early Bronze Ages, was the Middle Bronze Age II–III (seventeenth–sixteenth centuries BCE). The remains of stratum VI were limited to two child jar burials dated to MB III. One contained the bodies of two children, aged five and three, while the other contained an infant who died before reaching six months of age. The pottery placed within these two burial jars was most elegant in form.

Late Bronze Age. No architectural remains from stratum V, the Late Bronze Age I (fifteenth century BCE), have been uncovered at Tell el-Wawiyat. The limited ceramic repertoire associated with the stratum is best seen as reflecting the end of the Middle Bronze Age tradition.

The most common find attributed to stratum IV, the Late Bronze Age II (fourteenth–thirteenth centuries BCE), was ceramic vessels. Unexpectedly, there was a great deal of imported pottery, attesting to Tell el-Wawiyat's wealth and its cosmopolitan character during this period: most was Cypriot, including White-Slip milk bowls and vessels in Basering I and II, and Monochrome, White-Painted, and White-Shaved wares. A limited amount of Mycenaean pottery and one Minoan sherd were also found. Included among the vessels produced locally for domestic use was the typical range of cooking pots, storejars, and bichrome kraters.

A simple ceramic figurine showing a mother embracing her child was among the artifactual remains of the period. One building, originally constructed in LB II, but better known from the Iron Age IA, provides almost the full extent of the architectural evidence from this period.

The proximity of Tell el-Wawiyat to several other settlements, including the large city of Ḥinnatuni (modern Tel Ḥannaton) and the smaller Tel Qarnei-Ḥittin, as well as its wide range of imported wares, elucidates the nature of the LB II settlement. This hamlet was likely a way station under the control of Ḥinnatuni, supplying food and lodging to travelers and traders crossing the Lower Galilee.

Iron Age. Two stratum III (Iron Age IA, late thirteenth–twelfth centuries BCE) buildings separated by spacious open areas have been excavated. A large building in squares M–N in the northwestern quadrant of the excavated area was comprised of two main rooms and several smaller chambers. That this building was used for domestic activities is attested to by its assemblage of storejars, cooking pots, baking trays, and stands found with flint blades, basalt and limestone

mortars, grinding stones and pestles, and worked-bone awls and needles.

The building complex in squares K–L in the southeastern quadrant of the excavated area was originally constructed in LB II and remained in use in Iron IA. Its main room contained an unusual assemblage: a basalt and limestone jar stand, a stone column base, a ceramic oven, and hewn and plastered stone blocks. The partially articulated bones of a cow lay on the floor in a corner alcove. In another room a very large stone bin set into the floor was surrounded by a double wall. Among the artifactual remains were a spearhead, a steatite jewelry mold, a delicate basalt tripod, a broken Astarte figurine, and remnants of gold leaf. The K–L building complex, with these unusual objects suggestive of elite status, had a specialized, possibly cultic function.

That the Iron IA site evolved from its LB II predecessor is apparent in the ceramic and architectural continuity between the two periods. While Iron IA Tell el-Wawiyat was a farming hamlet, those living there led socially and economically complex lives.

In stratum II (Iron Age IB, eleventh century BCE), both stratum III buildings were modified: numerous small walls subdivided their spacious rooms. It seems, then, that in Iron IB, squatters, possibly early Israelites, reoccupied the abandoned Iron IA Canaanite village.

WEAPONS AND WARFARE. The earliest weapons found in the Near East are microlithic projectile points from the Mesolithic period, some, at least, of which were used as arrowheads. There is no evidence that these weapons were used for any purpose other than for hunting. The earliest evidence of fortifications is found in the Pre-Pottery Neolithic A settlement at Jericho. It was surrounded by a stone wall preserved to a height of 7 m which boasted an internal tower preserved to a height of 9 m. [*See* Jericho.]

Fortifications, which may be taken as evidence for the practice of warfare, appeared as early as about 4300 BCE at Mersin, in Cilicia, where a solid wall with projecting sections and simple interval towers was integrated into a ring of houses constructed on the wall's interior face. [*See* Cilicia.] The system featured a simple straight gate passage, flanked by towers. By 3000 BCE, the city of Uruk in southern Mesopotamia was surrounded by a fortification wall about 9.5 km (6 mi.) long, built, according to the Epic of Gilgamesh, by Gilgamesh himself. [*See* Uruk-Warka.] Excavations have not as yet revealed details of this monumental system. By 3000 BCE the cities of Egypt were fortified with massive, solid walls strengthened by equally massive solid interval towers, sometimes rectilinear and sometimes semicircular. Although there are no excavated examples, Egyptian gateways in later periods were always of the simple straight type, and it is likely that they were so in this period also. It appears that the Egyptians had not developed very sophisticated tactics in field warfare. They had, however, clearly made great advances in siege warfare, as tomb paintings show the use of siege ladders and an early version of the battering ram to create breaches in walls.

The first period for which there is extensive evidence of fortifications in the Levant is Early Bronze II, in which a number of towns were surrounded by single curtain walls, often with solid rectilinear straddle towers and external semicircular interval towers (e.g., at Arad, Ai, and Jericho). [*See* Arad; Ai.] The interval towers would have enabled the defenders to use enfilading fire against any attacking force, a major technological advance and necessary to the successful defense of a curtain wall. In EB III the fortifications of the towns of the Levant were strengthened and elaborated, to an astonishing degree, with the introduction of sloping ramparts (glacis) at the outer foot of fortifications and the use of covering walls in advance of the main curtain. Gates developed from the simple opening in the EB II curtain wall into straight and bent-axis external towers, sometimes with sloping access ramps angled so that an attacker approached the gate with the right (sword) hand nearest the curtain wall, leaving him unshielded against the fire from the defenders on the walls.

In about 2000 BCE, a sequence of events began which ultimately led to the revival of state-organized society in the Levant. Among the most important of these events were the collapse of the empire of the third dynasty of Ur (c. 2000 BCE) and the reunification of Egypt by Mentuhotep II (c. 1900 BCE). The first excavated evidence of fortifications in Egypt, the twelfth-dynasty fortress at Buhen, is from this period. It was a menacing highly sophisticated construction, with a multiple trace, straddle towers at the corners, interval towers along both the curtain and the covering wall, a scarp, and a counterscarp. The covering wall is fitted with arrow

slits. It is curious that in a fortress otherwise so sophisticated the gate is a simple straight passage, though flanked with massive solid towers. With the revival of Egypt came the revival of trade in the eastern Mediterranean and the revival of fortified towns.

Middle Bronze II A culture initially appeared in coastal Syria/Lebanon, from which it later spread southward to Palestine. Fortifications reappear in MB II A, with simple single trace-curtain walls. Little is known of the fortifications of this period. MB II B, however, saw the construction of the most impressive fortifications in the history of the Levant. The essential element of the system consisted of a dramatically enlarged version of the sloping ramparts first seen in the Early Bronze Age and now frequently faced with plaster, which sometimes extended into the matrix of the rampart as part of its construction. The plaster facing served two functions: in peacetime it protected the artificially steep slope from erosion, while in time of war it would have served to make the slope too slick to climb, especially if water were poured down it.

The transition between MB II A and B is generally agreed to be linked to a major political event—the fall of the Egyptian Middle Kingdom—although the exact nature of the link is still disputed. If the inscriptions of the New Kingdom pharaohs are taken at face value, Egypt was attacked and conquered by the armies of the kings of Syria-Palestine; however, these accounts were written hundreds of years later and are highly propagandistic justifications of the conquests by the New Kingdom pharaohs. At any rate, it is clear from both textual and archaeological evidence that Syro-Palestinian rulers took over Lower Egypt and ruled it for a period of at least a century. In this position they controlled Egypt's trade and wealth and their homeland prospered accordingly. This prosperity led to an increase in population unparalleled in the ancient Levant.

As settlements grew in size it became necessary to extend fortifications beyond the ancient tells. At sites such as Hazor, the largest settlement in the southern Levant, enormous artificial ramparts were constructed enclosing large areas of level ground which were then built up as part of the settlement. [*See* Hazor.] Because of erosion at the tops of the ramparts it is not clear whether the ramparts were crowned with walls in every case; however, in those cases where the top of the rampart is preserved, as at Jericho, there is evidence of a fortification wall on top of the rampart. At Gezer there is evidence of the use of a multiple trace, with a covering wall in advance of the curtain, as well as of the use of massive rectilinear straddle towers and a massive projecting solid tower gate with three internal piers. [*See* Gezer.] Elsewhere, the towers are chambered, but the use of three internal piers is general.

The transition from the Middle Bronze Age to the Late Bronze Age was also connected to a series of major political events. Once again, however, the precise nature of the connection is disputed. In about 1600 BCE the first dynasty of Babylon was brought to an end by conquest by the Hittite king Muršili I, and in about 1550 BCE Ahmose I, first king of the eighteenth dynasty of Egypt, expelled the Syro-Palestinian dynasts, known through an error of translation as the Hyksos, from Egypt. [*See* Babylon; Hittites; Hyksos.] Muršili I was assassinated on his return to Ḫattuša/Boğazköy, but Ahmose's successors, most notably Thutmose III, went on to conquer Palestine and Syria as far as the Euphrates River. [*See* Boğazköy; Euphrates.] The Levant thus fell within the Egyptian empire and became subject to Egyptian imperial policy. Archaeologically, these historical events are to be linked to the cultural shift from the Middle to Late Bronze Ages, although the dating of the archaeological shift in historical terms is still in question.

In weapons and warfare, as in most other cultural aspects, the Late Bronze was a continuation of the Middle Bronze Age. However, some very significant changes took place: at virtually every site in Palestine the massive MB fortification systems were abandoned, although at a number of the excavated sites (e.g., Lachish and Megiddo) imposing new gateways were constructed. [*See* Lachish; Megiddo.] These gateways do not appear to have had any defensive walls and would appear to have functioned ceremonially primarily. From the Amarna letters it is learned that order was maintained by small contingents of Egyptian troops; other Egyptian texts tell of an administrative system linked by messengers in chariots. [*See* Amarna Tablets, Chariots.] The absence of fortifications would appear to have been a deliberate Egyptian policy to prevent the rise of overly mighty subjects. One of the few exceptions was Hazor, where the MB fortifications continued in use throughout the Late Bronze Age. This has been taken by at least one scholar to indicate that Hazor lay outside the area of Egyptian control/interest. Another important exception is Ugarit, the great trading center on the Syrian coast, where a portion of the fortifications in front of the great royal palace has been excavated. [*See* Ugarit; Palace.] There the excavators found a massive solid tower with a gate tunnel whose construction owes nothing to the Levantine tradition of construction. It most closely resembles the postern tunnels in the fortification system of the Hittite capital Ḫattuša in central Anatolia—a simple, straight passage with a section consisting of a pointed, corbeled arch. This reflects both the importance of the Hittites in the Late Bronze and their dominance of northern Syria in the latter part of this period. The fortifications at Ḫattuša are among the most impressive in the ancient world, with a massive multiple trace, generally set at the top of a ridge, to give maximum advantage to the defenders. The main curtain is a casemate wall with massive chambered interval towers. The covering wall is solid, with smaller chambered interval towers set between the interval towers of the curtain. The gate passage is flanked by projecting massive chambered towers, with two internal piers,

and is approached from the right by a sloping ramp, to put attackers at a maximum disadvantage.

By the fourth millennium, two types of bow are known to have been in use. Mesopotamian pictorial depictions show a simple self-bow; Egyptians show themselves using a double-convex self-bow, possibly with the tips strengthened with horn. It is unlikely that these bows were compound. Curiously, there is little evidence for the bow and arrow in the EB Levant. The main weapons appear to have been the mace and the battle-ax, indicating hand-to-hand combat, rather than longer-range fighting. The existence of deep systems of fortifications, however, indicates that the bow must have been in use, along, probably, with the sling, which has a deadly accuracy to a range of at least 100 m. The heads of the arrows must have been of hardened wood.

It is debatable whether anything which could properly be called a sword was in use in the Early Bronze Age, although there were long, straight, double-sided stabbing daggers. The reason for the lack of swords is that these require a hard metal, at least bronze, and the only metal in use in the Levantine EB was copper. Thrusting spears and possibly javelins were also used in this period for massed infantry assaults. The most important weapons for hand-to-hand combat were the semicircular battle-ax and the mace: both were mounted on long, slender hafts, whose flexibility would have added to the force of the blow; both also were for use against soldiers unprotected by metal armor. Little is known of the conduct of armies in the field in Egypt, and nothing at all in the Levant, in this period. In Mesopotamia, however, it is clear that field armies were highly organized and used sophisticated tactics. The Stela of the Vultures, erected by King Eanatum of Lagash (c. 2500 BCE) shows his Sumerian infantrymen advancing in a true phalanx, protected by shields and armed with long thrusting spears. [*See* Girsu and Lagash; Sumerians.] This formation made the Sumerian armies a formidable fighting force in the absence of powerful long-range weapons. The phalanx of infantry was accompanied by mobile spearmen mounted in four-wheeled war carts drawn by teams of onagers. [*See* Carts.] These war carts lacked steerable front wheels and were slow and cumbersome, not to be confused with the chariots of the Late Bronze Age (see above). Their primary use was probably to break up opposing infantry formations in advance of an assault by the infantry.

In Mesopotamia, the period beginning in about 2200 BCE saw the introduction of a revolutionary new weapon, the composite bow, which is first seen in the hands of Naram-Sin, King of Agade. His armies, like those of his grandfather, Sargon the Great, reached as far as the Mediterranean Sea. Yigael Yadin (1963) suggests that this weapon, with its unprecedented range and power, was a major factor in these conquests. The collapse of state-organized society in the Levant at the end of EB III brought an end to fortifications, which were beyond the means of the agricultural villages which remained the sole form of human settlement. Nevertheless, there is clear evidence of conflict between these communities, in the form of an abundance of personal weaponry. Most male burials in Middle Bronze I/EB–MB/EB IV (as the period is variously known in the Levant) are accompanied by a distinctive form of dagger—long, slender, double edged, and weakly attached to the hilt by rivets. A more formidable weapon was the battle-ax, which was crescent shaped, with a cylindrical socket for the haft. In addition, numerous javelin heads and some stabbing spears have been recovered. A development which has recently been shown to have occurred in this period is the invention of the long slashing sword, of which only one example is known, currently preserved in the British Museum. This is an impressive weapon, nearly a meter long and double edged, with a sharp, piercing point. It is curious that this development appears to have had little or no influence, as such swords are nowhere depicted artistically. While most of these weapons could have had peaceful uses in hunting, the evidence currently available indicates that hunting played a very minor role in the economy of these communities. [*See* Hunting.]

Weapons underwent a certain degree of development in MB II. The crescentic battle-ax became heavier and generally had a socket for the haft. The advent of bronze body armor and helmets led to developments in the battle-ax, which became elongated and slender. Ultimately, it was reduced to a heavy armor-piercing spike, rather than the cutting edge it had been in the Early Bronze period. The widespread use of bronze also led to the development of the first swords, which were sickle shaped, with the cutting edge on the outside of the curved portion of the blade. This type of sword was also probably a development from the crescentic ax of the Early Bronze Age; like the ax, as distinct from the straight sword which supplanted it at the end of the Bronze Age, it could not be carried in a sheath, which made it less convenient than the latter form proved to be. The daggers of this period were distinctive, having a broad, veined blade attached to the hilt by rivets in a short tang. These daggers frequently had a crescentic pommel, often of stone. The type originated in Mesopotamia in the Early Bronze Age and in the Middle Bronze Age spread throughout the Near East and into Europe (those carved on the sarsen stones of Stonehenge, England, are the most far-flung examples). Javelins and socketed thrusting spears were also in widespread use, as were slings, known primarily through artistic depictions.

Although the compound bow had long been in use in Mesopotamia, surviving bows from Middle Kingdom Egypt, like the artistic depictions of bows, are all of the simple self-bow type, although some of them are slightly double convex. At some point, probably late in MB IIC/MB III, a weapon was introduced into the Levant which was to change the shape of warfare in the ancient Near East and become the most important tactical factor until the end of the Bronze

Age. This formidable weapon was the horse-drawn, two-wheeled war chariot. Lightweight and highly maneuverable, the chariot served both as an assault weapon to break up infantry formations and as a mobile firing platform. As the infantry had no answer to the onslaught of chariots, particularly when they were used en masse, they quickly came to dominate warfare. In the form in which they were introduced into the Near East they came from the steppes of Central Asia. The manual used for training horses throughout the region then is known for its Indo-European technical terms, including the equivalent of the medieval knight: the *maryanu* warrior, or charioteer. Yadin (1963) suggests that the deep fortifications which appeared at the beginning of MB II were the response to the introduction of this weapon. The view is not supported by the evidence from the Levant, however, which suggests that in this period society was feudal, dominated by a warrior aristocracy in which the most prestigious element was the charioteers. This is reflected even in the Egyptian New Kingdom, where the king was depicted as a charioteer, although the form of the society was very different. What is clear from the universality of massive and deep fortifications is that warfare was widespread in the MB Levant and that the wealth and power evident in the cities required the defense implied by their fortifications (although the identity of the enemy against whom the defenses were raised is not clear).

The Late Bronze Age saw only one significant development in Levanto-Egyptian small arms: the introduction of the compound bow from Mesopotamia. This was a formidable weapon, with a far greater power, range, and accuracy than any bow hitherto available to soldiers in the region. Amenhotep II is recorded as having shot at a copper target about 6 cm thick from his chariot, the arrows striking with such force that they went through the target and out the other side. Even allowing a certain degree of exaggeration to glorify the king, this is a significant demonstration of the power of this weapon. In addition, the compound bow had the advantage of being much shorter than the simple self-bows which had preceded it, making it the ideal weapon for use in chariots and by massed bowmen against infantry. When combined with units of slingers, units of bowmen greatly increased the fighting power of the infantry, although they still were no match for the power of the chariotry.

The end of the Late Bronze Age came shortly after 1200 BCE and was marked by one of the greatest political upheavals in world history: the collapse of both the Mycenaean and Hittite civilizations within the space of a few years. In the ensuing chaos there was a substantial invasion of the Levant by both a land army and a fleet of warships—the whole collectively known as the Sea Peoples, who very nearly succeeded in conquering Egypt and who took over the coastal plain of Palestine. These invaders brought with them a new series of weapons developed in western Europe in the course of the previous centuries: a new type of body armor consisting of overlapping bands of bronze and a new type of long, straight, double-edged slashing sword, stronger than the earlier Near Eastern model because of its single-piece (bilt and blade) cast construction. These weapons were not generally adopted by the armies of the region, however.

After an interval of a century (c. 1000 BCE) new, independent kingdoms began to emerge from the ruins of the Egyptian empire in the Levant. In coastal Syria and Lebanon the Canaanites, now becoming known as Phoenicians through their Greek contacts, began to establish a network of seaborne trading colonies, first on Cyprus and then farther west. [*See* Canaanites; Phoenicians.] For the first time since at least the mid-fifteenth century BCE, the cities of the Levant began to be fortified. The new fortifications were to some extent a revival of the ancient Canaanite tradition, but with innovations which arose from its redevelopment. Within the area which was to emerge as the Israelite kingdoms, a clear development sequence can be seen, beginning with villages in which the houses, built in a continuous ring around a central space, presented a blank external wall which formed a sufficient defense against small-scale attacks. [*See* House, *article on* Syro-Palestinian Houses.]

As the size of the settlements grew more significant, fortifications were required. These developed rapidly, possibly influenced by those of the Phoenician cities to the north. In detail, however, the fortifications of the Israelite cities were very different. From the beginning they involved the use of a multiple trace, with a curtain wall and an advanced covering wall. Interval towers provided enfilading fire; later, Assyrian bas-reliefs demonstrate that in time of war the coverage from the tops of walls and towers was increased by the addition of projecting wooden platforms. [*See* Assyrians.] Gateways became more formidable, with the addition of a fourth internal pier, and the gate tower itself was changed from a projecting bastion to an internal tower—with the advantage that it could not be surrounded by enemy attackers. The gate approach became much more of a defense in depth, with a series of towers and gates along the passage leading up to the main city gate at the top of the city mound. This approach was almost invariably from the right, thus exposing the sword side of the attacking soldiers to the flanking fire of the defenders on the walls. Curtain walls could be of either casemate or solid construction, as circumstances demanded. The use of ramparts with prepared surfaces also continued, sometimes with a plaster facing and sometimes with a stone facing.

A major technological development in this period, which had a profound effect on weapons and warfare, was the introduction of iron. The advantage of iron lay not so much in its hardness, which was no greater than that of bronze, as in its cheapness. Iron ore is found in most areas of the Near East, and, while the process of smelting iron is more complex than that required for copper, iron is far more abundant than the tin required to turn copper into weapons-grade

bronze. Iron arrowheads quickly become abundant, as did iron daggers and swords, enabling the arming of larger numbers of soldiers than ever before. Initially, warfare was little different than it had been throughout the Late Bronze Age, with large numbers of chariots supported by massed infantry, as can be seen in the account of the battle of Qarqar in 853 BCE, between Shalmaneser III of Assyria and a grand alliance of Syro-Palestinian kings (including Ahab of Israel, whose chariot contingent is recorded as having been the largest on the Syro-Palestinian side). This battle, however, can be seen as a turning point: it is the last major chariot battle recorded. Shortly thereafter, the Assyrians pioneered a new type of warfare which rendered the chariot-based armies obsolete.

The Assyrian infantry was organized into three types of unit: spearmen, bowmen, and slingers. The spearmen were the shock troops and carried a thrusting spear considerably longer than they were tall. The significance of this weapon is that it was the forerunner of the spears carried by the Greek phalanx and, when presented by the first two ranks of an infantry formation, made that formation invulnerable to a chariot charge—which would simply impale itself on the massed spears. Behind the spearmen came the bowmen and slingers, who, with their massed fire, could break up chariot attacks at long range before they came within range of the spearmen. These innovations were not the only, and not necessarily the most important, made by the Assyrians, however. From the beginning of the Bronze Age the towns of the Levant had been built on hilltops because of the defensive advantages of this elevation. It greatly increased the normal 2:1 ratio of attackers to defenders required for battlefield success. The Assyrians were the first to develop sophisticated siege machinery with which to attack the fortified cities of the Near East. Two weapons in particular are significant, the siege tower and the mobile battering ram.

The siege tower enabled the attackers to return defensive fire from a level as high as, or even higher than, that of the defenders. While this could not have suppressed the defensive fire generally, it could have suppressed it along a short stretch of the wall, which would have made the work of those attacking the wall itself much easier. The mobile battering ram consisted of a wheeled vehicle with a body covered in copper or leather armor in which the soldiers operating the ram could work secure from the fire of the defenders. [*See* Leather.] The ram itself was suspended from the frame of the body and consisted of a long beam with a metal head. The early models had an ax-shaped head, but the later models, following an experiment with boar's-head rams, consisted of a large spearhead. Regardless of the type of head, the method of operation was the same: the head of the ram was forced into the stone or brickwork of the wall and then used as a lever to pry the wall apart, causing it to collapse; a breach was thus created through which the infantry could attack. Israeli excavations at Lachish revealed the method of defense against these engines, which was to build a massive mound of earth and stone against the inner face of the wall in the sector being attacked by the rams. This countertactic did not succeed in saving Lachish, however, whose conquest Sennacherib appears to have considered his greatest victory.

The results of the Assyrian innovations were far-reaching. Perhaps the most noticeable result is that after the fall of the kingdom of Judah in 586 BCE, hardly any of the city mounds in the Levant were ever reoccupied by a major city. With the defensive advantages of elevation removed by the new siege machinery, the disadvantages of living on the top of the hills were all that remained. Henceforth, all cities were built on the level ground at the foot of the ancient tells.

The Babylonians, who succeeded the Assyrians in 612 BCE, and the Persians, who conquered Babylon in 539 BCE, made few changes in the military armamentarium, organization, and tactics laid down by the Assyrians. [*See* Babylonians; Persians.] The beginning of the use of mounted archers came in this period, but their initial impact was slight because two key technical developments—the invention of the saddle and the invention of the stirrup—had not yet taken place. The major innovation by the Persians was that, as a result of the vast extent of their empire, they were able to field huge armies, which enabled them to overwhelm any potential foe by sheer force of numbers. In their operations against Greece the Persians did, however, carry out combined operations—coordinated operations of the Persian army and the Phoenician fleet.

The Persian armies were routed in the second half of the fourth century BCE by Alexander of Macedon, who brought against them the new combination of the Greek phalanx, with its formidably disciplined troops armed with very long lances and protected by heavier armor and shields than any previous troops. The use of shields by the troops inside the phalanx to protect the front ranks (which deployed their lances against the enemy) from the missiles of the slingers and bowmen made this the most impressive fighting formation the world had yet seem. The additional use of cavalry to attack the flanks of the enemy gave Alexander a tactical advantage the Persians were never able to counter. It is significant that most of the battles fought by Alexander were in the field. His siege operations, as at Tyre and Gaza, were demonstrations of the superiority of the offensive over the defensive in fortifications in this period and account for the abandonment of the tells. [*See* Tyre.] The Greeks developed very sophisticated methods of naval warfare based on the bireme, trireme, and quinquereme, with, respectively, two, three, and five banks of oars. These ultimately enabled them to dominate the eastern Mediterranean in their competition with the Phoenicians. [*See* Seafaring.]

After Alexander's brilliant tactical innovations, the Hellenistic commanders, like the Babylonians and Persians who

followed the Assyrians, settled into an increasingly rigid tactical routine, based on the phalanx and flanking cavalry units. It was this increasing tactical rigidity which left the Hellenistic armies of the east vulnerable to the more tactically flexible and maneuverable Roman legion, a weakness demonstrated by the campaign of Pompey the Great in 63 BCE. Where the Hellenistic infantry had relied on its long stabbing spears, the Roman infantry relied instead on a short, straight, double-sided stabbing sword and a short, heavy stabbing spear which could also be thrown with accuracy up to 25 m. When the two types of formation first faced one another at the battle of Pydna, the legions allowed the phalanx to pass through their ranks and then closed in on it from all sides. Individual Roman soldiers slipped between the spears of the phalanx to attack the relatively defenseless Macedonian soldiers. To the battering rams and siege towers of the Assyrians the Hellenistic generals added *catapultae, ballistae, onagri,* and *scorpiones.* The first was a very large crossbow, capable of firing, dependent on the size of the engine—anything from a large arrow to a spear in a flat trajectory with great force and considerable range. The second was based on the same principle as the first but could throw much heavier weights in the form of large stones or beams. The *onager* used a long lever arm, powered, like the first tow engines, by twisted cords. The arm was wound down by means of a windlass, and when the trigger was released the slingstones, larger stones, or containers of burning oil or naphtha ("Greek fire") was hurled in an arc over the enemy fortifications. The *scorpion* could be either a kind of catapult or a miniature *onager.* In addition, the Romans used battering rams of the same type as those developed by the Assyrians; they used them to attack fortifications by means of mines which sought to bring down the overlying wall by creating a cave-in. The defenders of cities quickly developed the technique of countermining beneath the attackers' mine, to collapse the latter before it could collapse the overlying wall. The Byzantine military largely represented a continuation of the Roman military tradition, with its reliance on heavy infantry and limited use of cavalry.

In the seventh century CE, the armies of Islam burst out of Arabia and began a series of conquests which would take them to the gates of Constantinople, India, and, in the west, to southern France. These armies were, at least initially, both lightly armed and lightly armored, and their success was based largely on those factors. The Arab armies were superbly mounted as well, which gave them a mobility their Byzantine and Persian opponents could not match and with which they could not cope. In the course of the following centuries the Arab armies acquired an infantry arm. Influenced by the Byzantine fortifications they captured, they developed their own school of sophisticated fortifications, which were built by Salah edh-Din and his successors to counter the Crusader castles in the Holy Land.

WEIGHTS AND MEASURES. Insofar as it pertains to the ancient past, metrology (the investigation and theory of measurement) has two primary purposes: (1) to describe *systems* of measurement, and (2) to determine the *absolute values* of the various units of measure. This article describes how these two goals are accomplished and provides a brief historical overview of measurement in the Near East; references to works that describe systems and discuss absolute values are provided in the bibliography.

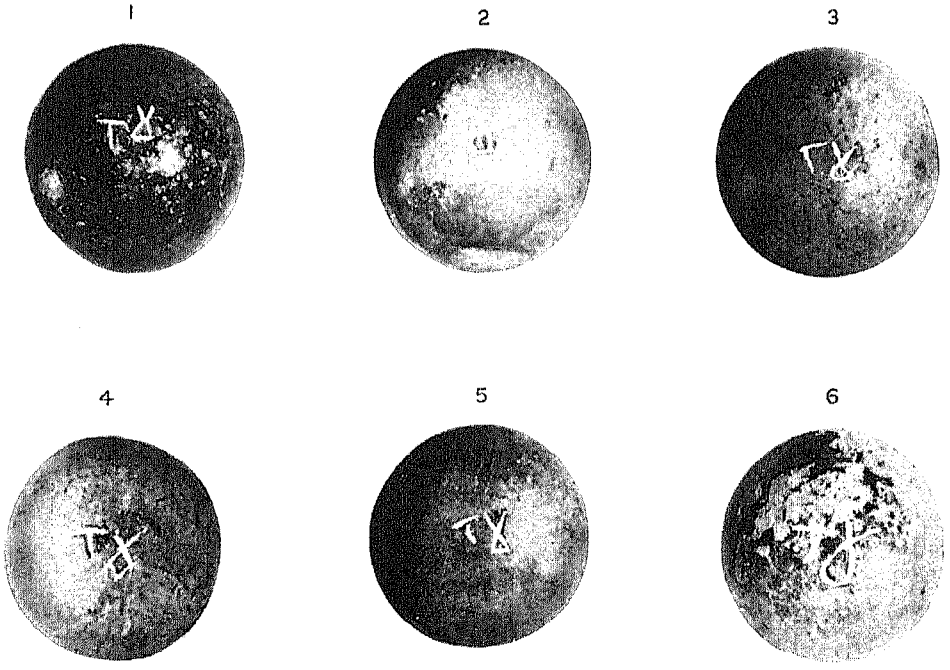
For the ancient Near East full systems of measure can be described only for Babylonia and to a lesser extent for Egypt. Where adequate written documentation exists, one can describe the *relative ratios* of components in a system of measurement, as, for example, 80 chains = 1 mile or 8 quarts = 1 peck. This kind of relationship can usually be inferred

from accounts that contain individual entries followed by totals and is best documented for Mesopotamia, from which we also have surviving tables of weights and measures. Linkage of one type of measurement with another, for example, 1 (wine) gallon = 231 cubic inches, is usually discernible only in textual sources. Mathematical texts sometimes utilize such linkages, and ancient authors occasionally mention these linkages. The extant mathematical texts from Mesopotamia and Egypt begin with the Middle Bronze Age, and linkages between types of measurement, for example, between length and capacity, are encoded in the number coefficients used in Babylonian mathematics. However, specific statements about the relationship of one type of measurement to another do not antedate discursive-narrative literature, of which the oldest surviving example of a complete work is that of the fifth-century BCE Greek historian Herodotus.

Determining *absolute values* for ancient measures means the process by which ancient units are equated with modern units. In stating modern equivalents the metric system is preferred because of its lack of ambiguity (there are, for example, still three measures in the range of 1 liter that are all referred to by the English term *quart*). Like all measurement, so-called absolute values are approximations, and the nature of the evidence at our disposal means that many of these approximations are rather imprecise. In using modern approximations of ancient units it is always advisable to reckon with the possibility of a ±5 percent margin of error; in some cases the margin of error will be smaller, but in other cases even greater. There are three major types of evidence upon which these modern approximations rest.

First, there are objects that represent ancient standards. Weights constitute the only unequivocal evidence of this type. Stone was preferred as the medium for weight standards in the Bronze Age. In the first millennium BCE a gradual shift to metals is evidenced by specimens, mostly of bronze and lead, and also by the noticeable diminution of stone weights. In the Byzantine and Islamic periods, glass was used for precision standards, but metal must have continued in use for making ordinary weights. For the Near East, the shift from stone to metal mediums has had the same ironic result as the shift from cuneiform to alphabetic writing: like clay, stone was relatively cheap and not easily re-formed, whereas most metal was probably melted down and recycled. This has led to disproportionately better representation for the Bronze Age than for later periods.

A small number of surviving weights are inscribed with their unit values and sometimes the name of the "owner" (usually a god or ruler), and some of these are preserved intact. By weighing these perfectly preserved, inscribed objects, the weight norms that they imply can be deduced. Sets of inscribed weights incorporating multiples or fractions of a single standard are not extant, and, in fact, the vast majority of all surviving weights are entirely without mark of any kind. Thus, the "units" represented by these various



WEIGHTS AND MEASURES. *Series of marked shekel weights from Lachish.* (Courtesy ASOR Archives)

objects have to be inferred from their masses alone. If the relative ratios of the underlying system are well known from written documentation, as in Mesopotamia, and if the mass of the object is in the 10-gram range or larger, it is usually possible to deduce the implied "unit" incorporated in an ancient weight specimen. Smaller units, however, are much more difficult to sort out, and these constitute a large portion of surviving weights.

A few extant objects of wood, stone, and metal represent ancient standard of length. Most of these are cubits (forearms) or portions of cubits, with divisions into palms of four or five fingers, and sometimes into fingers and smaller subdivisions. The three oldest datable examples are from Mesopotamia: two graduated rules showing a palm of five fingers and fingers divided into smaller subdivisions engraved on statues B (fragmentary) and F of Gudea (twenty-second century) implying the use of a cubit in the 50 cm (20 in.) range and a notched bronze bar found at Nippur, which is probably earlier than Gudea's reign (the cubit standard it seems to imply—518 mm (20.4 in.)—suggests a date prior to Naram-Sin of Akkad). For the Middle Kingdom through the Roman period (c. 2000 BCE–395 CE) in Egypt there are a few wooden and stone examples and, for the early Islamic period, there remains a gauge that measured the level of the Nile engraved on the rock wall of the island ar-Rauḍa/Roda (dated by inscription to 861 CE). The cubits implied by these objects fall in the 50–54 cm range. It should be noted, however, that none of the extant items incorporating standards of length possess the official character of the inscribed weights. Although some weights are inscribed with the unit and are said to be "true weight" or the weight of a god or ruler, nothing comparable exists for measures of length.

The situation for capacity measures is similar to that for length but is fraught with more uncertainties. Only wood and metal are likely to have been used for standard measuring vessels. Baskets may have been used for actual measurement but only after comparing them with true standards. However, no measuring receptacles of wood have survived, and none of the bronze vessels is inscribed with the unit it is supposed to represent. Another category of evidence compensates in part for the dearth of measuring vessels: these are jars or bowls of stone or pottery inscribed with a statement of the capacity. Absolute values for ancient capacity units rest primarily upon this type of evidence. However, an element of uncertainty always remains when using marked jars for metrological purposes. Because they were not intended to be actual standard measuring vessels, the "full" mark is never indicated. An added uncertainty is the level of accuracy in measuring, both by the ancient people who filled the jar and inscribed its contents and by the modern scholars who measured and reported them.

The second type of evidence that can be used, with caution, to establish absolute measures consists of uninscribed objects that incorporate repetitions of the same magnitude of measure and tell us that this magnitude had some metrological significance. This type of evidence is best exemplified by unmarked weight specimens, bricks for length measures, and pots of a more or less standard size for capacity measures. Such evidence, however, has never been systematically utilized, because many examples from specific locations and specific times have to be measured. With a sufficiently large sample, statistical analysis can be applied to the data, and the "inductive metrology" advocated long ago by W. M. F. Petrie can be practiced. Perhaps because of the prodigious amount of painstaking and tedious work, the potential of this evidence has never been realized. It seems likely that "inductive metrology" will continue for a long time in its current inchoate state.

The third type of evidence, which assumes importance from the fifth century BCE onward (and is especially important for the Islamic period), consists of statements by authors equating Near Eastern measures with Greek, Roman, Venetian, or some other better-known (at the time of the reference) measure. The value of this evidence depends upon the following: (1) the precision of the original approximation; (2) the degree of precision with which the "known" measure can be interpreted; and (3) the reliability of the manuscript tradition. Even where we can be relatively certain that the manuscript tradition is sound, the first two factors entail a margin of error that may vary significantly. These approximations are frequently accorded more value by modern scholars than they actually possess.

It remains to summarize the history of weights and measures in the Near East. This can be divided broadly into three periods: prior to the invention of writing around 3000, between about 3000 and Alexander the Great (c. 330 BCE), and after Alexander.

For the first period, clay counters or tokens and the earliest Mesopotamian script imply measurement of some type. It seems probable that systems of length measures based on body parts like the forearm and the hand and on related time-distance measures like a day's journey as well as on locally accepted units of capacity were widespread in the Near East in the late fourth millennium, though nothing certain can be said. The many local standards that appear in later eras may well reflect survivals of "prehistoric" measures. However, given the difficulties of describing even textually documented standards, it is unlikely that any of the "prehistoric" metrological systems can be accurately reconstructed.

The second period is characterized by a few dominant systems reflected in relatively abundant records written in Mesopotamian cuneiform (and its relatives) and in Egyptian hieroglyphs and hieratic, as well as by a limited amount of material ("monumental") evidence. These dominant sys-

tems are best known for Babylonia in the era from the Akkad Empire through Old Babylonian (c. 2300–1600) and, to a lesser extent, for Egypt from the twelfth through the twentieth dynasties (c. 2000–1100). These systems owed their dominance to the following two factors: (1) they were embedded in the system of writing and were passed along as a part of the scribal craft; and (2) centralized administrations (temple and palace) had a vested interest in recordkeeping. These forces tended to foster standardized systems of measurement, and these systems clearly had considerable effect upon measurement even beyond the economic world of the temple and palace. Despite occasionally expressed opinions to the contrary, there is, however, no evidence for any attempt to enforce universal metrological standards. Of these two systems, the influence of the Babylonian was more widespread, coinciding approximately with the use of cuneiform. The precise nature of this "influence" remains unclear. A common theme of older (and occasionally of newer) works on ancient metrology was the "migration" of "standards" from one place to another, for which Babylonia was a favorite source of derivation. These theories were spun largely in the absence of written evidence. When we have both written and material evidence, as in northern Mesopotamia, Elam, Syria, and Anatolia, however, it is clear that the Babylonian system was adapted rather than wholly adopted. It is not even clear that the numerous "mina" norms in the range of 450 to 525 grams were derived from Babylonia.

The third era begins with the Macedonian Greek conquest of the Near East and continues up until relatively recent times. Greek conquest of the Near East had three important results for the history of metrology. First, it accelerated the tendency to abandon the traditional Bronze Age scripts of Mesopotamia and Egypt for the more practical alphabet. Second, the metrological systems of the ruling Greeks, and later of the Romans who followed them, gradually spread widely in the Near East. Third, the spread of coinage led to the development of metal monies of nominal value. All three factors have affected our ability to describe the metrology of this era. The widespread adoption of the alphabet over the first millennium BCE radically reduced the survival of ancient economic records (upon which we primarily depend for reconstruction of metrological systems) because alphabetic writing was primarily used on perishable materials and has survived only in exceptional climatic conditions like those of Egypt. Whereas coinage provides an additional type of evidence for weight metrology, the development of nominal-value coinage, where the name of the coin bears no relationship to its actual weight (a significant break with earlier tradition), greatly complicates the study of weight standards. It was this complex metrological world that the Arabs inherited when they conquered the Near East in the seventh century CE. When Arabic literary sources begin to become fairly abundant in the ninth century, they indicate the existence of many local standards and systems of measurement, and this undoubtedly reflects realities that are simply not recorded in the extant ancient written evidence.

MARVIN A. POWELL

WEILL, RAYMOND (1874–1950), French Egyptologist and archaeologist who headed a scientic expedition sponsored by Baron Éduard de Rothschild to the southern

part of the Ophel hill (City of David, Jerusalem), in 1913–1914 and 1923–1924. Weill was born in Elbeuf, France. He was an officer in the Corps of Engineers, after which he studied history and philology, at the age of thirty, and earned a Ph.D. from the École Pratique des Haute Études. He worked with Flinders Petrie in the Sinai Desert as well as at other sites in Egypt and was co-founder of the French Egyptological Society.

Weill was the first in Jerusalem to expose a wide excavation area rather than dig tunnels, as earlier explorers in the city had done. He uncovered Roman quarries that had damaged earlier remains, among them two long, vaulted horizontal rock cuttings, reached via shafts. Weill identified the hewn areas as the tombs of the Judean kings. The assertion generated serious differences among scholars, but the cuttings are not considered to have been tombs.

Weill's most significant discovery was a Greek inscription mentioning two synagogue leaders, Theodotus and his father, Vettenos. Assigned paleographically to the Second Temple period, the inscription is important evidence that synagogues coexisted with the Jerusalem Temple.

Following his first campaign in the City of David, Weill returned to France to take part in World War I. He was severely wounded in battle, for which he was awarded the Legion of Honor.

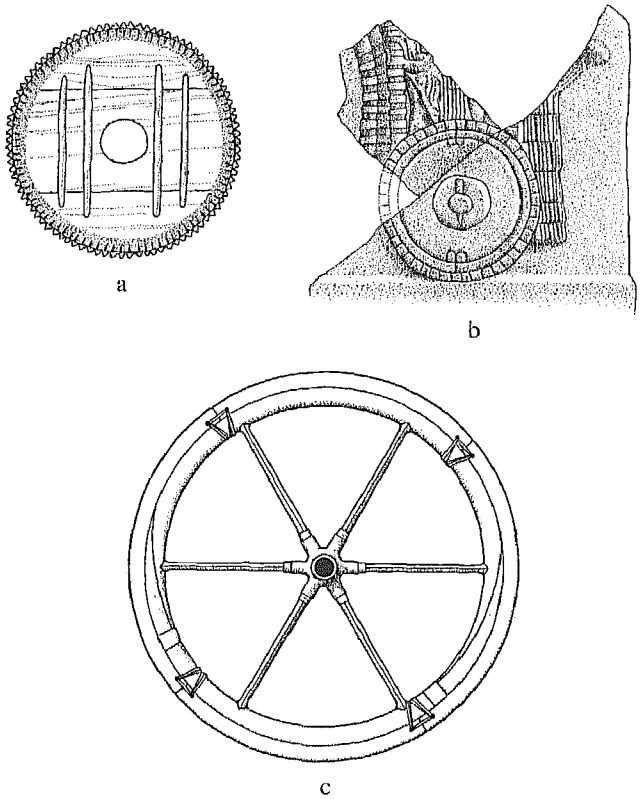
RONNY REICH

WHEEL. Archaeological evidence for the wheel appears in the Near East as early as the Early Dynastic II period (c. 2750–2650 BCE). Earlier pictographs from Uruk level IVa (c. 3100 BCE) show sledges raised over what are either two captive rollers or four disk wheels. Remains of actual wheels were found in graves at Kish, Ur (Early Dynastic III), and Susa (figure 1a) in the mid-third millennium. These were all tripartite: made of three planks cut vertically from a tree trunk and held together by external battens as well as by rawhide, with wooden or metal tires (from 0.50 to 0.83 m. in diameter) that were sometimes hobnailed. This construction is considered a response to a shortage of wide boards of local timber. The wheels appear to revolve on fixed axles.

A variation of this wheel first appears on a stela of Gudea in the Ur III period (figure 1b), in the late third millennium. It shows what seems to be a relatively small solid wheel rimmed by two metal half tires with hobnail tread, secured

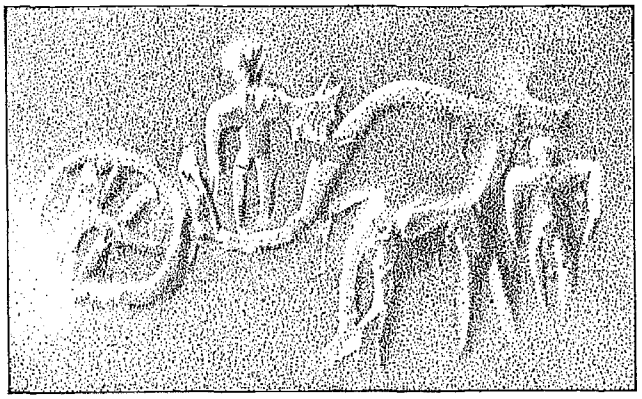


WHEEL. Figure 1. *Wheel types.* (a) reconstruction of a wheel type from graves in Kish, Ur, and Susa, mid-third millennium BCE; (b) depiction of a wheel on a stela of Gudea, late third millennium BCE; (c) drawing of a six-spoked wheel surviving from eighteenth-dynasty Egypt. (After Littauer and Crouwel, 1979)

by clamps at their ends. Actual metal tires in six or seven segments, with a clamp at either end and one in the middle, indicate disk wheels with diameters of 0.67–0.97 m. These come from early second-millennium Susa, Aššur, and elsewhere.

Of lasting significance were attempts to lighten the disk wheels, as first seen on a third-millennium seal from Hissar IIIB (figure 2). On it, the central plank, through which the axle passes, is narrowed to a diametral bar; the flanking planks of the tripartite wheel are eliminated, and the former bonding slats are turned into sturdy transverse bars between the diametral bar and the felloe. This crossbar wheel is also clearly illustrated in the second millennium BCE, fixed on a revolving axle; it has remained in use with simple carts in various parts of the world. [*See* Carts.]

By far the most important innovation was the spoked wheel, which first appeared with four to eight spokes, in Anatolian and Syrian glyptics and other graphic remains from the early second millennium BCE. Actual four- and six-spoked wheels (figure 1c) survive from eighteenth-dynasty Egypt. These have composite spokes made from single rods, half oval in section, and heat bent in the middle to form an



WHEEL. Figure 2. *Depiction of a wheel on a seal from Hissar IIIB.* Third millennium BCE. (After Littauer and Crouwel, 1979)

angle (of 60 degrees for a six-spoked wheel and 90 degrees for a four-spoked one). The "legs" are glued back to back to the "legs" of the adjacent spoke, the resultant whole spoke being fully oval in section. The wider diameter of the spoke is set at right angles to the felloe, which is composed of two lengths of heat-bent wood, overlapping at the ends. Rawhide, applied wet, constricted and solidified the naves and felloes. This construction, based on tension and without metal parts that could be jolted loose, required great skill to make and was vulnerable to dampness. It is attested in Egypt, the Levant, and the Aegean.

A spoked wheel based on a different principle is illustrated in Assyrian reliefs of the early first millennium BCE. [*See under* Chariots.] Its six or eight spokes are simply set in a cylindrical or barrel nave, which may be a metal case, with short tubular projections to receive the spoke ends. The deep felloes are made of butt-ended sections of plank, their inner edges lying in a metal channel. Such a wheel is the ancestor of all later wooden spoked wheels.

Practically nothing is known of the impact of the earliest wheels in Mesopotamia in the late fourth millennium BCE. From Early Dynastic II and III remains at Kish and Ur it is clear that the shortage of timber of adequate girth imposed the tripartite disk construction and, that, lacking iron for tires and battens to consolidate them, the wheels cannot have been very strong. Because wood axles were also limited in the weight they could bear, it is unlikely that wheeled vehicles were used to transport heavy goods. What pack animals could not carry would have been transported by sledge, for which there is ample evidence from fourth-millennium tablets from Uruk to seventh-century BCE reliefs of Sennacherib, and from actual finds and tomb paintings in Egypt from the twelfth dynasty to the twenty-first dynasty.

Third-millennium representations in Mesopotamia show disk-wheeled vehicles in military, hunting, cult, and travel contexts only. Evidence for their use in warfare, for which they were clearly unsuitable, fades rapidly after the middle of the millennium. That wheeled vehicles were considered prestigious is clear from their burial in richly furnished graves (Kish, Ur, Susa). Their economic and political impact seems to have been negligible, but because possessing them demonstrated conspicuous expenditure, it could reinforce social ranking.The appearance, in about 2000 BCE, of the spoked wheel and horse draft—both essential for the true chariot—did not produce a suitable military vehicle immediately: the team's harness and its control had to be improved first. Evidence for this appears initially on early Syrian seals of the eighteenth century BCE.

The use of the chariot in warfare undoubtedly affected military strategy, but its impact may have been less than first appears, for several reasons. Because infantry always accompanied chariotry, campaigning speed could hardly change. Analysis has also shown that chariot tallies were often inflated. Furthermore, much of Near Eastern terrain is mountainous, rocky, marshy, or sandy—unnegotiable for chariots yet, the prestige of the chariot—costly to make and maintain—was enormous, enhancing the standing of all chariot owners. Economically, it stimulated the growth of several occupations: wheelwright, carriage maker, armorer (charioteers wore more body armor), and horse breeders and trainers.

WHEELER, MORTIMER (1890–1976), one of the legends of archaeology in the twentieth century. Born in Glasgow, Scotland, to a journalist and his wife, Robert Eric Mortimer Wheeler was called Eric in his youth. His first wife, Tessa Verney, with whom he had one son, called him Rik, or Rikky, by which he was known for the rest of his life.

There are two Wheeler autobiographies, *Still Digging* (London, 1955) and *My Archaeological Mission to India and Pakistan* (London, 1976), both of which reflect many of the strengths and weaknesses of the genre, and one biography, Jacquetta Hawks's *Adventurer in Archaeology: Biography of Sir Mortimer Wheeler* (New York, 1982).

Wheeler focused his early scholarship on the remains of Roman Britain. In 1907 he entered University College London, where he earned an M.A. and D. Litt. After World War I he went to the National Museum of Wales as keeper; he became director in 1924. In 1926 Wheeler became director of the London Museum. His two most famous excavations of this period were at Verulamium (1930–1933) and Maiden Castle (1934–1939), where he perfected his field methodology and trained students. From this post he played a major role in establishing the Institute of Archaeology at London University. In 1943, while on military service in World War II, he was posted to India as the director general of the Archaeological Survey, where he served until 1948.

The government of India gave Wheeler a broad mandate, and he undertook the complete reform of its archaeological enterprise. This involved more training of students and establishing a school of archaeology, which remains active today as the Institute of Archaeology, New Delhi. He also carried out four training excavations: in the early historic city of Taxila (1944–1945); at the Roman trading emporium of Arikamedu (1945); in the Indus city of Harappa (1946); and of megaliths and Early Historic remains at Brahmagiri-Chandravalli (1947). Wheeler returned to the subcontinent to excavate Mohenjo-Daro (1950), another Indus city, and Early Historic Charsada (1958), both in Pakistan. He was an innovative digger and his writings on field methodology, especially *Archaeology from the Earth* (Oxford, 1954), are important contributions to excavation methodology.

After India, Wheeler became a public figure, although he still lectured at the university level. A brilliant participant on the BBC game show "Animal, Vegetable, and Mineral," he became Britain's television personality of the year in 1954. He also served effectively as a tour leader, bringing groups to ancient sites in the classical world, the Near East, India, and Pakistan. His base for many years was the British Academy, where he was a long-time honorary secretary (1949–1968).

Wheeler's personality was flamboyant, even theatrical. He was a leader, a man given to command, but quick to anger, and he could be insensitive and difficult with those around him. The honors he received in his lifetime were many: commander of the Indian Empire (1947), a knighthood (1958), and honorary degrees from a number of British universities.

GREGORY L. POSSEHL

WILSON, CHARLES WILLIAM (1836–1905), British Royal Engineer (1855) whose meticulous surface survey of Jerusalem (Ordnance Survey of Jerusalem, 1864–1865) provided the basis for all subsequent studies of the city. Wilson served as secretary to the North American Boundary Commission (1858–1862), during which time he gained invaluable survey experience. In the course of his military career as a major-general, he held many prestigious appointments, among them director of the Topographical Department of the War Office (1870–1876), British consul general in Anatolia (1879–1882), chief of the Intelligence Department in Garnet Wolseley's force in Egypt (1882–1885), and director general of the Ordnance Survey of Great Britain (1886–1894). He was a Knight of the Garter, Knight Commander of Order of St. Michael and St. George, and a fellow of the Royal Society. He earned honorary Doctor of Civil Law (Oxford, 1883) and Doctor of Laws (Edinburgh, 1886) degrees.

Wilson's survey work led to the founding of the Palestine Exploration Fund (PEF) in 1865. The £500 contributed by Baroness Burdett-Coutts to the cost of this project did not include the pay of the officer in charge, but Wilson accepted the appointment for the War Office, even though he believed it to be a fool's errand. Jerusalem was surveyed according to standard Ordnance Survey practice, at scales of 1:500, 1:2,500, and 1:10,000. The resulting plans, not just of the whole city, but also of important buildings, together with ninety diagrams and eighty-three photographs, were published by the Ordnance Survey in 1866. It was the first time that the topography of Jerusalem had been so accurately recorded. In 1865–1866 Wilson, with Samuel Anderson, undertook a reconnaissance survey of Palestine, during which Wilson was the first to identify the synagogue at Chorazín. His other archaeological forays, such as to Capernaum, Mt. Gerizim, and Kefar Bir'am, were superficial investigations; however, the plans he made of these places remain a valuable record of the sites as they were in the nineteenth century.

Wilson went on to carry out the survey of Sinai (1868–1869), concluding that Jebel Musa was the true Mt. Sinai. In 1871 he prepared the guidelines for the Survey of Western Palestine (1871–1877), commissioned by the PEF. In the last six years of his life he turned his attention to resolving the controversy surrounding the identification of the sites of Golgotha and the Holy Sepulcher. His findings, published in several papers in the PEF's *Quarterly Statement*, were published separately by the PEF in London in 1906, under

the title *Golgotha and the Holy Sepulchre,* a book still highly regarded. Wilson was chairman of the PEF at the time of his death.

YOLANDE HODSON

WINNETT, FREDERICK VICTOR (1903–1989), Canadian philologist, archaeologist, biblical scholar, and educator. Born in Oil Springs, Ontario, Winnett studied under W. R. Taylor and Theophile Meek at the University of Toronto. He was ordained to the Presbyterian ministry in 1927, and a year later completed his Ph.D. dissertation, the translation of and commentary on a manuscript copy of the thirteenth-century Nestorian Abdiso bar Berka's *Paradise of Eden* (published in 1929). A postdoctoral fellowship at Hartford Theological College enabled him to continue advanced studies in Arabic, Akkadian, and Hebrew. He married Margaret J. Taylor and in 1929 was appointed lecturer in Semitic languages at University College, the University of Toronto.

Winnett's career took a decisive turn when he was shown a black basalt stone with a Thamudic inscription (now in the Royal Ontario Museum). His systematic and insightful study of the hundreds of inscriptions in pre-Islamic scripts already published was the pivotal *A Study of the Lihyanite and Thamudic Inscriptions* (1937; see also Albright, 1937). In 1938 he held the post of honorary lecturer at the American School in Jerusalem. A difficult and dangerous field expedition with the school's director, Nelson Glueck, to collect sherds in the Wadi Zerqa marked his introduction to archaeology and the Transjordan, both of which, with one exception, were to be his principle foci for the coming decades. [*See the biography of Glueck.*]

Following World War II (during which he served in the Canadian army as a drill instructor, with the rank of 2d lieutenant), Winnett wrote a series of articles on Himyaritic inscriptions for the *Bulletin of the American Schools of Oriental Research,* together with articles relating these texts to biblical interpretation. Under Meek's influence his major interest during this period, however, was the formation of the Pentateuch. This eventuated in *The Mosaic Tradition* (1949), an attempt to deal with the materials as a unified tradition. Despite its hostile reception by the reigning adherents of the Documentary Hypothesis, Winnett was to revisit this hypothesis in his presidential address to the Society of Biblical Literature in 1964 (see Winnett, 1965).

In 1950–1951 Winnett returned to the American School in Jerusalem as director, continued the excavations begun by James L. Kelso at Tulul Abu el-ʿAlaiq (Kelso, 1955) and initiated soundings, followed by full-scale excavations the following spring, at Dhiban, biblical Dibon (1964). [*See* Dibon.] Winnett also undertook two expeditions with G. Lankester Harding, then director of the Jordan Department of Antiquities, to northern and southern Jordan in search of inscriptions. These resulted in *Safaitic Inscriptions from Jordan* (1957) and "An Arabian Miscellany" (1971). [*See the biography of Harding.*]

In 1957 Winnett assisted James B. Pritchard in clearing the lower portions of the great circular water system at El-Jib, biblical Gibeon. [*See* Gibeon.] Returning again as director of the American School in Jerusalem in 1958–1959, he and Harding made two expeditions to north Jordan, where they recorded some four thousand Safaitic inscriptions, some of which were published in *Inscriptions from Fifty Safaitic Cairns* (1978). Subsequently, Winnett and William L. Reed (who again served successive directorships), accompanied by Aramco's anthropologist, F. S. Vidal, engaged in an adventurous month's expedition locating ancient monuments, recording inscriptions (Winnett) and collecting pottery (Reed) in the wilds of North Arabia. The highly impressive results together with a gripping journal of their adventures, were published in *Ancient Records from North Arabia* (1970). In 1962 Winnett again joined Reed for exploratory soundings at El-ʿAl in the Transjordan. A second major expedition to Saudi Arabia was mounted in 1967 (Winnett, 1970).

From 1952 to 1969 Winnett was chairman of the Department of Oriental Languages of University College, University of Toronto. Under his leadership that small department became a world-class university Department of Near Eastern Studies. Later the Department of Middle Eastern and Islamic Studies was separately organized. From 1966 until his retirement in 1969 Winnett also served as vice-principal of University College. During this period he was active in facilitating the publication of Lankester Harding's *An Index and Concordance of Pre-Islamic Arabian Names* (1971). His latest publications were "Studies in Ancient North Arabian" (1987) and a contribution to the *Festschrift* of Mahmoud Ghul (1989). It is a measure of the man that much of his active retirement was spent caring for his beloved wife.

Winnett was elected a Fellow of the Royal Society of Canada in 1959. He was active at many levels in the American Schools of Oriental Research, including a brief stint as editor of its annual. He was president of the Society of Biblical Literature in 1963–1964 and a member of the editorial

board, a member of the American Oriental Society, the Archaeological Institute of America, and a charter member of the Toronto Oriental Club. Following his death, his family and friends initiated an American Schools of Oriental Research fellowship in his name. As good at administration as he was in the desert or at his scholar's desk, Winnett was an honest, warm-hearted, and courageous human being who inspired and enabled others to do their best.

JOHN S. HOLLADAY, JR.

WOOD. Forests were exploited from the very beginnings of Near Eastern civilization. Enough hints exist from such Aceramic Neolithic sites as Jericho in Israel and Çayönü, Aşıklı Höyük, Nevalı Çori, and Hallan Çemi in Turkey to indicate that extensive forest use has a history in this region of at least ten thousand years. These sites provide ample burned evidence for architectural timbers used as building foundations, headers and stretchers in walls, roof posts, roofs themselves, ladders, and furniture. Although the evidence is sometimes to be assessed only by counting empty beam holes, enough burned beams survive at Middle Bronze Age palatial sites such as Kültepe (Kaneš) or Acemhöyük in Turkey so that a reasonable estimate for wood use is in excess of 2,000 trees per 150-room building. The archaeological evidence includes cedar, pine, fir, juniper, oak, spruce, cypress, box, chestnut, walnut, maple, and ash.

Forests. The Lebanon, Anti-Lebanon, Amanus, Taurus, Anti-Taurus, Pontus, and Zagros Mountains probably provided the bulk of quality timber for construction and fine furniture, especially after local wood supplies were exhausted. There is reason to believe, however, that some local supplies—for example, from the Anatolian plateau—were sufficient for most needs, at least until Hellenistic times. At all times lesser-quality woods—poplar, willow, plane, tamarisk, sycamore, elm, beech, and acacia—or wood for specialized uses, such as terebinth, and assorted fruit and nut trees must also have been exploited for ordinary carpentry, fuel, and pottery production. Wood products such as resins were used in treating illness, in mummification, and for caulking boats. [*See* Jericho; Çayönü; Nevalı Çori; Taurus Mountains; Kaneš.]

Wood Production. The surviving architecture at many sites shows considerable use of wood in a wide range of quantities and quality. Much of the wood was probably local, especially for sites on the Anatolian plateau, along the Levantine coast, and in the forested areas mentioned above, where it could be dragged to a site by ox cart. At Gordion in Turkey, cuttings exist in the logs that form the tomb chamber of the Midas Mound Tumulus that reflect precisely this form of timber transport. [*See* Gordion.] In Egypt and Mesopotamia, however, good wood had to be imported by water. As far back as Old Kingdom Egypt, timber was transported from Lebanon to Egypt in multiple shiploads. At all times, timber must have been floated down the Tigris and the Euphrates Rivers to Mesopotamian cities. The occupations or crafts of woodcutter, timber transporter, timber merchant, and carpenter must have been established from the very beginnings of civilization. Cuneiform texts indicate that royal authorities were concerned about regulating timber cutting, setting timber prices, and imposing taxes on timber.

Timber Trade. The oldest surviving written evidence for an international timber trade is the Palermo stone, in which Snefru, the first pharaoh of the fourth dynasty, tells of im-

porting cedar from Lebanon: "Bringing forty ships filled [with] cedar logs. Shipbuilding [of] cedar wood, one . . . ship, 100 cubits [long] [= 45.73 m], and of *meru* wood, two ships, 100 cubits [long]. Making the doors of the royal palace [of] cedarwood." The text does not specify a place of origin, but Byblos is likely. It is worth noting that the actual word translated here as cedar is *ash* wood or *'š* wood in the texts; there is less than total agreement among Egyptologists that the word does indeed mean "cedar." *Meru* may mean cypress or juniper. One school of thought proposes that the Egyptians did not make a distinction between cedar and juniper, and that *ash* refers to better-quality conifers and *meru* refers to some kind of second-quality timber. At any rate both *ash* and *meru,* whatever they may mean, are foreign (imported), usually sold in long lengths, and thus readily distinguished from the local acacia or sycamore. This wood was put to refined uses: shipbuilding and making palace doors. Philologists may argue about the meaning of the words *ash* and *meru,* but archaeologists do have large quantities of identifiable cedar and some juniper in the Egyptian collections of the world's museums.

In dockyard accounts from the time of Thutmosis III (c. 1450 BCE), a fragmentary papyrus in the British Museum records the issuing of timbers to the workers. The parts of the ship for which the timbers were intended (which ought to help identify them) are also given; however, the meaning of all the maritime terms is not known. Four times as many *ash* timbers as *meru* timbers are required, suggesting that whatever *ash* really is, it is straight, pliable, and free of knots—and thus suitable for shipbuilding. The longest timber specified was of *ash,* 30 cubits long (13.72 m), and intended for the mast. *Ash* is required for masts in other documents, and again the lengths are quite long: 40 cubits (18.29 m) and 42 cubits (19.21 m).

No doubt the import and export of high-quality wood goes back even further than these Old and New Kingdom references. That international timber production and marketing were not occasional adventures is attested by the much later report of Wenamun. That the king of Byblos in Wenamun's tale could produce three hundred woodcutters upon demand, as well as sufficient animals and drivers to drag the timbers down to the port, suggests that both he and his woodsmen were accustomed to the practical requirements of the timber business and to fulfilling large foreign orders. A tour through any Egyptian gallery in a Western museum corroborates the texts, revealing a mixture of both local and imported wood on the more elegant of their sarcophagi, furniture likely to be cedar, and domestic objects likely to be riverine wood, such as sycamore, tamarisk, and acacia.

The earliest Mesopotamian reference to cedar is from Sargon of Akkad (c. twenty-third century BCE), who claims that the god Dagan gave him the Upper Country (i.e., Mari), Iarmuti, and Ebla as far as the Cedar Forest and the Silver Mountain. One of his successors, Naram-Sin, has the god Nergal give him Arman and Ebla, and also the Amanus, the Cedar Mountain, and the Upper Sea. [*See* Akkade; Mari; Ebla.]

In a military campaign into Syria and Cilicia Shalmaneser III (ninth century BCE) demands as tribute from one prince one talent of silver, two talents of purple wool, and two hundred cedar logs. Another prince in the Amanus, somewhat poorer, must send metal, cattle, two hundred cedar logs, and two measures of cedar resin at once, and annually thereafter one hundred cedar logs and one measure of cedar resin. A third prince has to include three hundred cedar logs annually. Sargon II (late eighth century BCE) not only uses the timber for taxes, but also places an embargo on sale of it to the Egyptians and other inhabitants of the Levant. Depictions on Assyrian royal reliefs confirm the textual account, with men hauling and floating large logs down from the mountains to Aššur. [*See* Aššur; Assyrians.]

Ashurnasirpal (883–859) has left the most detailed records of the logging activities of the Assyrian kings. His men cut four kinds of trees: *erenu, šurmenu,* and *dapranu* in the Lebanon and Amanus, and *burašu* in the Amanus only. The information regarding Assyrian names for wood is not much better than for Egyptian names. It is believed that *erenu* is *Cedrus libani,* although the arguments are complicated; *dapranu* is a kind of juniper, as is *burašu,* although the latter has also been identified as cypress; and *šurmenu* is probably cypress (see essay by Postgate in Postgate and Powell, eds., 1992). It is known that the words refer to wood because they are preceded by a Sumerian logogram, GIŠ, meaning "wood." GIŠ.ERIN.MEŠ (= cedar) seems more certain than the others, however, particularly because of the Wadi Brisa inscription of Nebuchadrezzar: in it he claims to have built a road and a canal to carry "mighty cedars, high and strong, of precious beauty and of excellent dark quality (?), the abundant yield of the Lebanon, as [if they be] reed stalks [carried by] the river" (Wadi Brisa inscription of Nebuchadrezzar in Brown, 1969, p. 199).

On the other hand, if it were not for the immediate proximity of Wadi Brisa to the cedar forest, the text could refer to *Juniperus excelsa,* which also has red or "dark" wood, as well as to cedar. The Assyrian inscription in Wadi Brisa is of additional interest because only 50 m away, on the wall of the wadi, a Roman inscription (one of about two hundred that encircle the remaining cedar forest but now about 1.5 km downhill from the forest edge) from near the end of the reign of the Roman emperor Hadrian, (c. 134 CE) delimits the forest boundary. Hadrian's procurators had marked this off as a very special forest, and the public was officially informed that four genera were not to be cut. Whether these are the same four genera mentioned in the Assyrian text only 50 m away is not known. At any rate, the cedar forest boundary did not change significantly, at least in Wadi Brisa, for more than seven hundred years. The present deforestation is a post-Roman phenomenon. A scrap of evidence from the western edge of the Near Eastern world, and from a much

later time, is that the cedar for the treasury doors at Eleusis (in central Greece) was supplied, at vast expense (seventy days' wages for a 2″ × 4″ × 12′ board), by an *emporos,* an overseas trader and merchant from Knidos, in Caria.

Wood Use. Although evidence for constructional timbers of all classes is the most commonly found demonstration of the use of wood in antiquity, furniture is an obvious but less-common use. Fine furniture, indeed, is rare, except for the remarkably well-preserved inlaid wooden furniture at Gordion. Stone furniture, such as funeral beds, can be presumed to be copies of wooden furniture. Enough furniture inlay exists elsewhere—of ivory or bone or metal—at Aššur, for example, to show that elaborately carved and decorated furniture was more common than the archaeological record might otherwise suggest. Almost every Urartian site has produced elaborate metal furniture fittings—bronze animal feet and terminals, silver or gold medallions, plaques, and other attachments both practical or ornamental—and the lists of booty taken by the Assyrian kings include furniture of boxwood and ebony embellished with gold, silver, and ivory. Painted furniture representations on Greek pottery are another important indirect source of information.

Shipbuilding as an activity speaks for itself (see above). Every ship lost at sea, whether accidentally or in a naval engagement and then replaced, must have represented a drain on forest resources. Cedar timbers with up to four hundred annual rings from a twelfth-dynasty Egyptian ship, the so-called Dahshur boat now in the Carnegie Museum in Pittsburgh, Pennsylvania, one of five funerary vessels found near the pyramid of Senwosret III, and therefore presumed to belong to the time of Senwosret (c. 1860 BCE) at Dahshur, are clearly cut from enormous trees—some centuries old and probably the size of standing trees found today in the Lebanon and the Taurus ranges. In what was an extremely wasteful woodcutting practice, the timbers were carved or sculpted to shape, not bent, as can be seen on a representation of boat builders at work on a relief in the tomb of Ti (fifth dynasty) at Saqqara, Egypt. At least half the wood was thereby lost. [*See* Ships and Boats.]

Carpentry. Almost every tool—from the crude to the sophisticated—known to modern carpenters was used by the ancients: axes, adzes, hammers, mallets, wedges, chisels, drills, lathes, right-angles (or T-squares), plumb bobs, compasses, planes, rasps, and polishing agents of various kinds. Evidence exists for the use of almost every modern technique as well: mortising, tenoning, treenailing, beveling, gluing, and intricate joining and inlaying. A glance at the more elegant pieces of the Gordion furniture (eighth century BCE) should remove any doubt about the skill and sophistication of the ancient carpenter, not only in the craftsmanship thereby demonstrated, but also in the selection of a half-dozen species of wood for their contrasting colors and textures and the assemblage of thousands of such fragments into an agreeable whole.

PETER IAN KUNIHOLM

WOOLLEY, C. LEONARD (1880–1960), British archaeologist, excavator of Ur in Mesopotamia. Educated at St. John's School, Leatherhead, and at New College, Ox-

ford, Charles Leonard Woolley was appointed in 1905 to be assistant in the Department of Antiquities in the Ashmolean Museum under Arthur Evans. His life's occupation was set in 1907, however, when he joined the Eckley B. Coxe Expedition of the University of Pennsylvania Museum in Philadelphia (now the University Museum) to excavate at Karanog, Nubia, a Meroitic (Hellenistic) cemetery, and at Buhen, a second-millennium fortress, under David Randall-MacIver. He remained with the Coxe expedition until 1911 and joined an Oxford University expedition to Nubia in 1912. Woolley was then chosen to succeed D. G. Hogarth as director of the British Museum's excavations at the important Syro-Hittite site of Carchemish in north Syria. Apart from a six-week survey between seasons on behalf of the Palestine Exploration Fund in Sinai conducted together with his Carchemish colleague T. E. Lawrence in 1914 and an interruption for war service, Woolley continued at Carchemish until 1919. During the war he served as an intelligence officer in the Near East; but from 1916 to 1918 was a prisoner of war in Turkey.

After Carchemish, Woolley excavated on behalf of the Egypt Exploration Society at Amarna in Egypt from 1921 to 1922 and was then invited by the British Museum and the University of Pennsylvania Museum to lead a joint expedition to the site of al-Muqayyar (ancient Ur) in southern Mesopotamia.

Woolley is probably best known for the Ur excavations, carried out between 1922 and 1934, particularly for the rich treasures of the Sumerian Early Dynastic period found in the so-called royal cemetery. Woolley also completed the excavations begun by H. R. H. Hall of the British Museum at the small neighboring Sumerian site of Ubaid. Woolley conscientiously prepared ten volumes of his final report on the Ur excavations, but apart from volumes 1 (al-Ubaid), 2 (royal cemetery), 3 (seals), and 5 (ziggurat), these lay in typescript in the British Museum (7–9) and the University Museum (4, 6, 10) throughout the war, and were only published when funds became available from the 1950s through the 1970s.

After his knighthood in 1935, Woolley began excavations at Tell ʿAtchana in north Syria, the site of ancient Alalakh, in 1937. Once again he was interrupted by war. Although he was too old for active service, he served during 1943–1946, with the rank of lieutenant-colonel, as archaeological adviser to the Civil Affairs Directorate. On Woolley's advice the Allied supreme commander-general, Dwight D. Eisenhower, issued an order prohibiting the looting or damaging of buildings in liberated territories.

After his war service, Woolley resumed his work at Alalakh, completing the uncovering of second-millennium palaces and archives of cuneiform tablets, and, at the neighboring coastal site of al-Mina, he revealed evidence of early Greek settlement. Nearly seventy years old when he closed the Alalakh excavations in 1949, Woolley published a full report on the work there in 1955 and a popular account, *A Forgotten Kingdom*, in 1953. Woolley remained an influential figure in the world of archaeology. His last work, *Mesopotamia and the Middle East* (1961) was published posthumously.

T. C. MITCHELL

WRIGHT, GEORGE ERNEST (1909–1974), field archaeologist; architect of American "biblical archaeology"; president (1966–1974) of the American Schools of Oriental Research (ASOR); articulator of biblical theology as the recital of God's mighty acts in history; and mentor to two generations of archaeologists and interpreters.

Ernest Wright combined archaeological theory and practice with the bearing of archaeological results on biblical interpretation. The product of a Presbyterian ministerial family in Ohio, his education at the College of Wooster (B.A., 1931) and at McCormick Theological Seminary (B.D., 1934) nurtured a warm but critical Calvinist perspective and a love of Bible and history. His curiosity about the hard and social sciences led him to study with William Foxwell Albright at Johns Hopkins University, where he focused on the ceramic materials of the Neolithic, Chalcolithic, and Early Bronze periods. His dissertation on these materials updated by him and modified by his students and colleagues, remains a basic resource: he published it (New Haven, 1937) and an article on eisegesis and exegesis in the same year. For Wright, this combination of endeavors always made sense.

Wright had his first field experience in 1934 at Bethel, with Albright; during breaks, he roamed the land to gain a sense of its topography. In 1937 he worked with Elihu Grant at

Haverford College bringing order to the ceramic record of 'Ain Shems/Beth-Shemesh. [*See* Beth-Shemesh.] In 1938 he became field secretary of ASOR. That year he launched *The Biblical Archaeologist,* aimed at interpreting archaeological findings for amateurs. For years he and his wife, Emily DeNyse Wright, prepared it out of their home. As its editor for twenty-five years, he contributed thirty-six articles and innumerable short notes and reviews.

From 1939 to 1959, Wright taught Hebrew Bible at McCormick Seminary in Chicago. Early in that period he participated in Henri Frankfort's prehistoric seminar at the Oriental Institute of the University of Chicago; motivated by his appreciation for Robert Braidwood and others in that seminar, his interest in the "lower" tiers of historical study germinated: social history and environmental history. Meanwhile, he wrote three biblical monographs: *The Challenge of Israel's Faith* (Chicago, 1944), *The Old Testament against Its Environment* (Chicago, 1950), and *God Who Acts: Biblical Theology as Recital* (London, 1952). In each, he interfaced archaeologically informed historical interpretation with theological claims. Following up his topographic interest, he produced, with his New Testament colleague Floyd V. Filson, the durable *Westminster Historical Atlas to the Bible* (Philadelphia, 1945). In 1957 he published *Biblical Archaeology,* his portrayal of archaeology as a resource for biblical history and religion; included was a chapter on archaeology and everyday life—an expression of archaeology in the service of social history.

In 1956 Wright joined Bernhard W. Anderson in inaugurating the Drew-McCormick Expedition to Tell Balaṭah/Shechem in the Central Hill Country 64 km (40 mi.) north of Jerusalem. Their aims were to recover data from an earlier, ill-published expedition by Ernst Sellin under Austro-German sponsorship; to train and forge a network among a new generation of field archaeologists; and to practice the soil-deposition field method. Strong on practice, developing its theory as it worked, the Shechem team provided field experience to the future directorships of the Gezer, Tell el-Ḥesi, Ta'anach, Heshbon (Ḥesban), Caesarea, and Ai expeditions. [*See the independent entries on each of these sites.*] In 1959 Wright accepted the Parkman Chair of Divinity at Harvard University, where his graduate seminars nurtured budding archaeologists as well as a host of biblical specialists. His undergraduate courses introduced a multitude of inquisitive students to how biblical studies interacts with archaeology and the social sciences.

In 1964 he yielded Shechem to his colleagues, took a sabbatical in Israel, and launched, with Nelson Glueck, the Gezer Expedition, staffed by his Harvard protégés. There he began to bring hard and social scientists onto the staff, a vision fulfilled at Idalion, on Cyprus, in his most ambitious endeavor (1971–1974). [*See* Idalion.] With his acceptance of the presidency of ASOR in 1966, Wright came to influence all American archaeology in Southwest Asia; his students currently fill many of the offices of ASOR.

Wright's synthesis of biblical archaeology and biblical theology made for controversy among his students and his colleagues. His positivistic historical stance was vulnerable to attack by literary critics. The way he wedded history to divine manifestation was cogently challenged by theologians (see Gilkey, 1961). His archaeological expertise was accepted and esteemed by all, but some of his efforts at interpretation, notably of the Shechem results in relation to the patriarchal stories in *Genesis,* were questioned by those who found him deficient in interpretive theory.

By his expertise and by the sheer force of his personality, G. Ernest Wright pioneered one era, led in the transition to another, and left an unquestioned legacy of inquisitiveness and adaptable encounter with new insights and methods. Usually one jump ahead of his students, he never abandoned his efforts to make archaeology interdisciplinary and both available and accountable to all.

EDWARD F. CAMPBELL

WRITING AND WRITING SYSTEMS. Writing is a system of more or less permanent marks representing a set of utterances in such a way that the utterances can be recovered more or less exactly without the intervention of the utterer. This definition is worded to exclude such "forerunners" of writing as petroglyphs and the "tokens" found in excavations throughout the ancient Near East. Intuitively those are qualitatively different from the earliest systems that are indubitably writing, such as Mesopotamian cuneiform and Egyptian hieroglyphs—that is, a written message represents language, not thought. A necessary (though not sufficient) condition for the/an invention of writing is civilization, including urbanism; writing is prerequisite to history. And the first things to be written within any civilization tend to be things that cannot be expressed orally—accounts, calendars, and divine messages.

Nature and Origin. A forerunner, which perhaps expresses "thought," becomes a writing system (or script) when it has incorporated a means of recording the phonology of the language with which it is associated: a large proportion of the lexicon of any language comprises elements that cannot be represented by "thought pictures" of concrete objects, such as abstracts, function morphemes (e.g., inflections, prepositions), and—perhaps primarily—proper names, especially foreign names (native names are generally not meaningless, like *Jones,* but stretches of text, like *Carpenter, Farmer,* or *Smith*).

Two varieties of marks have recently been suggested as forerunners of true writing in the ancient Near East: the Vinča script and the Mesopotamian token. The former comprises markings incised on votive objects—figurines, models, vessels—excavated originally at sites in Transylvania and subsequently elsewhere in the Balkan region. Two hundred and ten different designs have been cataloged (Gimbutas, 1991, pp. 308–321). There are three difficulties in taking Vinča script as underlying either Sumerian cuneiform or the Aegean family of scripts: although its partisans refer to its marks as "writing," there are apparently no recurring sequences of signs, which indicates that if the marks are indeed representational, at most they represent things or "thoughts," rather than words; evidence of connections with the later and/or distant civilizations of the Aegean and Mesopotamian regions has not yet been established; and there is little hope of determining, let alone reconstructing, the language(s) that might have been spoken by the marks' creators.

Great attention was accorded in the 1980s to the claim by Denise Schmandt-Besserat (in a series of articles published between 1977 and 1988, many collected in Schmandt-Besserat, 1992) that the hundreds of "small clay objects," or tokens, excavated throughout the Near East, and which in some ways resembled the impressions found on the earliest clay tablets from Uruk, were in fact an early recording system: the tokens that looked like the later sign for *sheep* in fact represented sheep; some number of them enclosed in a lump of clay (a bulla) represented a flock of that number of sheep; as a security measure, each token was pressed into the clay, leaving a mark, before it was sealed into the bulla; finally, the impressed marks took the place of the enclosed tokens, and writing had been invented. Schmandt-Besserat identified dozens of token shapes with proto-cuneiform signs. [*See* Tablet; Uruk-Warka; Cuneiform.] Her theories were provocative and suggestive, but upon publication of her database (1992, vol. 2), Paul E. Zimansky (1993) was able to determine that the actual attestation of tokens does not square with the meanings imputed to them: from samples covering some seven thousand years, only eight "sheep" have been found, and from the fourth millennium only twenty-seven "textiles" of eleven kinds. These quantities do not make sense in the context of the economy revealed in later true cuneiform documents. Zimansky summarizes, "There is no reason to assume that tokens stood for specific commodities in ways that remained constant over the millennia in all parts of the Near East. It is less strained to suggest that various people at various times exploited the few geometric shapes that are relatively easy to make in clay and used them as counters or for whatever other purposes they, as individuals, chose" (p. 516).

An origin of writing that derives from the nature of the languages recorded has been suggested (Daniels, 1992b) that applies to the three societies in which writing emerged: Sumerian, Chinese, and Mayan. In each case, the language spoken was largely monosyllabic—that is, morphemes (meaningful units) were generally only one syllable long. This is significant for two reasons. It is commonplace for preliterate societies to make pictographic records, in which a picture stands for an idea, an event, or even a word; and psycholinguistic investigation shows that the basic unit of perception of speech is not the phoneme (roughly equivalent

to the sound represented by a letter of the alphabet), but the syllable. In a monosyllabic language, drawing a pictogram of a word is the same as making a sign for a syllable. Many of the abstracts, function morphemes, and proper names (see above) will also be monosyllabic, homophonous with picturable content words. The pictograms of the latter can thus easily be taken to represent the former as well. If words were more than a syllable long, the likelihood of homophony would be much reduced, and the unpicturable stretches of language would remain unrecorded. An early example is the Sumerian sign for *ti,* "arrow," which also stands for *ti,* "life." [*See* Sumerian.] It is noteworthy that every time someone not previously literate in any language has invented a script for his own language (the best-known example from more than a dozen cases is Sequoyah's Cherokee), the result is a syllabary.

Typology. Orthodoxy has it that there are just three types of writing systems: logographic, syllabic, and alphabetic. This typology seems to have been devised by Isaac Taylor (1829–1901); it achieved apotheosis in the work of Ignace J. Gelb (1907–1985), who asserted that the three types represent an immutable evolutionary sequence in the order named. That is, an alphabet can only develop from a syllabary, and a syllabary can only develop from a logography (Gelb, 1963, p. 201). Inasmuch as an alphabet has only been invented once in all the world, this is a rather incautious claim. It required Gelb to insist that the Northwest Semitic script, traditionally called an alphabet, is actually an "unvocalized syllabary" because the Ethiopic (and Indian) script that developed from it by altering the forms of the letters to denote vowels, is a hybrid that could not have developed from an alphabet.

These convolutions disappear when it is recognized that there are not three script types, but six: logosyllabary (purely logographic notation is not yet writing); syllabary; abjad (consonantary); alphabet; abugida (Ethiopic type); and hangul (feature based). (Abjad is an Arabic word; abugida is Ge'ez; and hangul is Korean.) Logosyllabaries include Mesopotamian cuneiform, Egyptian hieroglyphics, Anatolian hieroglyphics, Chinese characters, and Mayan glyphs. [*See* Egyptian.] Syllabaries include the Cypriot script and, par excellence, the Japanese kana. There is historically but one abjad, represented by its modern developments Arabic, Hebrew, and Syriac script. Again, only one alphabet has been devised, the Greek, ancestor of the diverse scripts of Europe. The abugida principle remains in use throughout South and Southeast Asia (seen in Sanskrit and Hindi Devanagari, and Thai, and all the other scripts derived from ancient Indian Brahmi) and in Ethiopia. The hangul type appears in Korean, in varieties of shorthand, and in general in scripts devised by scholars familiar with practical phonetics.

In a logosyllabary, several hundred to several thousand different characters each represent a morpheme, and a restricted subset of these are used purely for their phonetic value. In Sumerian cuneiform and Egyptian, phonetic complements are written alongside logograms to assist in interpreting signs that may have acquired more than one related meaning. In Chinese, on the other hand, a sign that provides phonetic information is incorporated into an individual character along with one that provides semantic information (so that the full inventory of Chinese characters is much larger than that of Mesopotamian cuneiform). In both Sumerian and Egyptian, further disambiguation is provided by semantic determinatives—characters that label the associated word as designating a member of a general class, such as textile, cattle, or city (e.g., in the Akkadian DINGIR. UTU = *aš*: DINGIR = the determinative for deities, UTU = the logogram for "sun," *aš* = the phonetic indicator for the pronunciation *samaš,* "sun deity").

In a syllabary, each character represents a syllable, almost always of the shape consonant + vowel (CV), or vowel alone. (Mesopotamian cuneiform, in fact, seems unique in allowing VC and CVC characters as well.) The number of characters is on the order of one hundred, being about the number of consonants in the language times the number of vowels. Owing to their derivation from logograms, signs that are phonetically similar generally show no graphic similarity. Where a syllabary has evolved from a logosyllabary, it may retain a limited number of logograms, as in Linear B, but the primary burden of communication is carried by the phonetic signs.

The evolution of writing systems thus far follows a fairly natural course, based in the nature of language and the nature of speech. It is the step to the consonantary that represents the greatest achievement in the analysis of language. Some lone genius had to recognize both that syllables do not differ unsystematically from one another—they could be classed into a small number of groups based on the similarity of their more prominent portions, their vowels—and that the portions of syllables that distinguish those with the same vowels from each other in turn bear some kind of similarity. This similarity is not acoustic, it is articulatory; it characterizes what are called consonants. It is possible that this recognition was the work of a Semitic-speaker because in the Semitic languages the consonants and vowels that make up words vary independently—the vowels are largely conditioned by the grammar. In Sumerian, however, a root always involved the same combination of consonants and vowels. In Akkadian, such a recognition is found only rudimentarily in the *ta-ti-tu* list of signs. [*See* Akkadian.] The consonants-only recording of Semitic was no impediment to reading, given the common assessment that redundancy in language is about 50 percent. Eventually, however, Semitic languages came to be invaded by foreign loanwords that did not respect the division of labor between consonants and vowels. The term *abjad* is offered in complementarity to *alphabet,* acronymically formed from the first letters of the Arabic

script in their ancestral order. (Abjad is the Arabic name for that sequence, which is still used when the letters serve as numbers.)

The developmental path of writing systems then branched when scholars speaking languages from two Indo-European families attempted to write them using forms of the abjad. The earlier result had been the *alphabet,* devised for Greek on the basis of a Phoenician or Aramaic model. [*See* Greek; Phoenician-Punic; Aramaic Language and Literature.] Given the paucity of both early Greek writing and Semitic texts, it is not possible to decide exactly when, where, or how the first attempts to write Greek took place (Pierre Swiggers in Daniels and Bright, 1996, sec. 21). A compromise date is about 800 BCE. Likely sites are trading posts, either Semitic-speaking in a Greek area or Greek-speaking in a Semitic area. (The suggestion of al-Mina, Cilicia, seems to rely on excavational accident rather than positive evidence, since it was merely the most prominent site that happened to be found at the right place and time.) The "how," is that, by a happy coincidence, the Semitic languages employ a number of consonants ("laryngeals") not found in Greek. Some of them apparently were heard by Greeks to color *a*-vowels in the direction of the *e* and *o* of their language: *h* and *ḥ* were used for short and long *e*, ʿ for *o*, and the inaudible ʾ for *a*. The letters *w* and *y* became *u* and *i*, suggesting an Aramaic influence (there, but not in Phoenician, those letters could stand for vowels even if they did not result from historical alteration of diphthongs). An alphabet is thus a script in which each consonant and vowel has its own symbol. This is the ideal state of affairs, and it tends to exist only when an alphabet is first devised: speech is fluid, continually though gradually changing as it is passed from generation to generation and as language communities drift apart; whereas script is fixed, because of the existence of writings from earlier generations and because the craft of writing is passed on in the normative setting of schools. [*See* Scribes and Scribal Techniques.]

In India, the Brahmi script is attested from the fourth century BCE, but in a fully worked-out form, suggesting that it had been devised some centuries before—most likely on the basis of a Semitic abjad. In Brahmi (and also in Kharoshthi, found in the northwest of the subcontinent and clearly based on the local Aramaic variety of abjad), which seems first to have recorded Prakrit and gave rise to the scripts of India and Southeast Asia, the vowels of the Indo-Aryan languages are denoted by appendages to the basic form of the letters. [*See* Indo-European Languages.] The base form does not, as in the underlying abjad, denote just the consonant; rather, it denotes the consonant plus the vowel *a*. A diacritic is available to cancel the vowel and indicate that the letter is used for the bare consonant (Richard Salomon, in Daniels and Bright, 1996, sec. 30). The same method of denoting vowels is found in Ethiopic script, except that a vowelless consonant is denoted by the same symbol as denotes the consonant plus shwa. Continuing the pattern of *abjad* and *alphabet,* a suitable name for this type is *abugida,* again taken from the native name for the characters when taken in their traditional order. (The available English names all incorporate the term *syllable,* misleadingly suggesting a similarity between this type and the syllabary.)

The sixth type of script is first seen in the Korean writing system, hangul. There, letters for phonetically similar phones receive graphically similar shapes, so that it is phonetic features rather than segments that are recorded. Only sophisticated linguistic scholars have created such scripts, which tend to serve special purposes, such as shorthand or phonetic notation.

By the middle of the first millennium CE, scholars of languages using abjads found it advisable to explicitly notate vowels in their texts. The first to do so, writing Syriac, were familiar with the Greek alphabet, but they chose not to add vowel letters to the sequence of consonants for two reasons: in all three abjad languages, the texts—Hebrew Bible, Syriac Peshitta, Arabic Qur'an—were sacred in their physical instantiations (not just in their content), and it would be sacrilegious to alter the received texts by interjecting additional letters. The seventh-century Syriac scholar Jacob of Edessa did in fact propose a full set of vowel letters to be written within words, but they found no favor because they would render all existing literature unreadable. Instead of full letters, textual scholars devised various systems of notating vowels (and other information) that involved placing symbols above, below, between, and even within the inherited letters. The Syriac traditions came first, then the Arabic, and finally, and most elaborately, the Hebrew. [*See* Syriac; Arabic; Hebrew Language and Literature.]

History. The historical development of writing systems largely follows the typological sequence described above.

Logosyllabaries. The first true writing of which specimens have survived is Sumerian cuneiform in its early stages (c. 3200 BCE). Piotr Michalowski (1993) offers evidence that its invention can be localized in Uruk: in the earliest city lists, the name *Uruk* is represented by the sign for "city" itself—that is, Uruk is the city par excellence. The earliest surviving documents are various kinds of lists and then what have come to be known as economic documents—the ephemera of running a temple, farm, or cattle ranch. At first only full words are recorded, then grammatical affixes (taking advantage of the phonetic properties of the signs). By early in the third millennium, cuneiform could record ordinary prose and poetry. With full phonetic capacity came the possibility of its use or adaptation for languages other than, even unrelated to that for which the script was devised. By the middle of the third millennium, the "Sumerian" script was in current use for writing Akkadian and Eblaite. [*See* Ebla Texts.]

Akkadian became the regional vernacular, while Sumerian was maintained as a language of religion and scholarship. With the adaptation of a script to a new language, as happened when cuneiform moved to Akkadian, the signs could

take on a whole new set of phonetic values derived from the new words associated with the same semantics; the inventory of logograms was reduced, and phonetic writing became more prevalent. Eventually, some genres of text eschewed logograms almost entirely, while writers on more arcane topics preferred to render their records confidential by writing in almost nothing but logograms—which required years of study to master. With the further spread of cuneiform (to Elamite, Hittite, Hurrian, Urartian), logogram use became ever more sparse, so that some cuneiform languages were written almost purely syllabically. [*See* Hurrian.] In Hittite and Hurrian, the practice arose of duplicating the vowel of a CV syllable with the sign for the matching V (even for phonologically short vowels), so that a syllable denoting a consonant followed by a vowel might in practice be designating the consonant only (Piotr Michalowski, Jerrold Cooper, and Gene Gragg in Daniels and Bright, 1996, sec. 3).

From Egypt, almost simultaneously with the earliest writing in Mesopotamia, appear the earliest surviving traces of (proto-)hieroglyphic writing, most notably the Narmer palette. The general similarity between hieroglyphic and cuneiform writing (logography, phonetic complements, semantic determinatives) leads most scholars to recognize influence from the latter on the former. Direct borrowing seems ruled out by the nature of the Egyptian script: the phonetic signs denote only consonants, never syllables. The signs represent three, two, or one consonant, and there is no indication whatsoever of the accompanying vowels. (The uniconsonantal signs, eventually numbering twenty-four, are often called an alphabet, but this group was never—until some late experiments in imitation of Greek writing—used as a system to the exclusion of bi- or triconsonantal signs.) The principles of writing Egyptian did not change for more than three thousand years; the hieratic and demotic scripts are cursive and extremely cursive versions of hieroglyphic, which continued to be used and elaborated in formal contexts until the end of the Egyptian civilization (Robert Ritner in Daniels and Bright, 1996, sec. 4).

In eastern Anatolia, perhaps influenced by the Linear A or B scripts of the Aegean, or perhaps by Egyptian hieroglyphics, a pictographic script was used for the Luwian language, a close relative of Hittite. It incorporates a limited number of logograms and is primarily syllabic (Craig Melchert in Daniels and Bright, 1996, sec. 6). [*See* Luwians.]

Abjad. Some time, probably in the second quarter of the second millennium BCE, some scribe, somewhere in the Levant, made the momentous discovery that words could be represented not for their meaning alone, nor according to their syllables, but that the syllables could be further broken down into a vocalic portion and a consonantal portion, and that the words could be represented by their consonants alone. As with Egyptian, this may have been practical because of the structure of the Afro-Asiatic languages (among them Semitic and Egyptian), where much grammatical derivation and inflection is accomplished by varying vowels accompanying consonantal roots (though it is incorrect to claim that all semantic information is in the consonants and all grammatical information is in the vowels). The fallacy must be avoided, however, of insisting on an Egyptian background or origin for the Canaanite abjad on the grounds that among the thousands of hieroglyphs it is possible to find a handful that look like the posited earliest forms found in the abjad: only when both the form and the function (i.e., sound value) of signs match—consistently across the system—can a relationship be claimed. At most, as with cuneiform influence on hieroglyphics, it can be said that the idea of writing consonants rather than syllables could have come from Egypt. The popular claim that the Proto-Sinaitic inscriptions underlie the abjad/alphabet, as codified by William Foxwell Albright (1966), depends on four unproven assumptions: the script is alphabetic, the signs have Egyptian prototypes, the letters are pictographic and acrophonic (i.e., they picture an object whose name begins with the sound denoted by the sign), and the language is Semitic (Sznycer, 1975). Moreover, its advocates do not explain why a group of putative Semitic-speaking miners at work or enslaved in the Sinai desert would have devised a script of their own—or how it could have reached or found general acceptance in Palestine. [*See* Proto-Sinaitic.]

Wherever and however the abjad originated, it found widespread adoption for recording a variety of dialects of the West Semitic language groups: Canaanite, Aramaic, and South Semitic. This last group used a script that diverged early on and is found in difficult-to-date graffiti in North Arabic languages ancestral to Classical Arabic and in beautiful, monumental inscriptions in Old South Arabian dialects. (This script was eventually taken across the Bab el-Mandeb to form the basis of Ethiopic writing.) The Northern Linear, or Canaanite, script (sparsely attested) developed into the Phoenician, which traveled all around the Mediterranean and beyond; it gave rise to the Punic script of Carthage and environs; appeared as an archaic, sacred script in the Dead Sea Scrolls (the Tetragrammaton in some texts was written in these archaic characters within a text otherwise in Square Hebrew script); and survives as the distinctive Samaritan script. [*See* Dead Sea Scrolls; Samaritans.] The script for Aramaic texts diverged somewhat and then followed two paths of development: one maintained the original separation of the letters (adopted, probably during the Babylonian Exile, for Hebrew and still in use) and the other, as a result of increasingly speedy writing, manifests increasingly cursive features. Its descendants include the surviving Arabic, Syriac, and Mandaic scripts, in all of which nearly all the letters of each word are joined (M. O'Connor in Daniels and Bright, 1996, sec. 5). [*See* Mandaic.]

In those languages that used the Aramaic abjad (but also in Hebrew inscriptions prior to the change of script), a means of denoting some vowels emerged gradually. At first,

word-final vowels were indicated with the letter for the homorganic consonant (i.e., ⟨y⟩ for [i], ⟨w⟩ for [u], ⟨'⟩ or ⟨h⟩ for [a]); subsequently, word-medial vowels could be so indicated. These optional consonant letters are known by the Latin term *matres lectionis,* "mothers of reading."

The first script known to have been invented rather than developed from an earlier one is Old Persian cuneiform, devised specifically to record the exploits of Darius the Great. The characters are composed of wedges, in imitation of cuneiform writing, but the script has been found only incised on building stone and cliff faces, never written on clay. Some characters render CV syllables, others plain consonants, showing the influence of both the Akkadian syllabary and the Aramaic abjad (David Testen in Daniels and Bright, 1996, sec. 8).

The earliest sizable corpus written with a form of the Levantine abjad is the Ugaritic texts, which survived because they were written on clay tablets with a reed stylus in imitation of Mesopotamian practice. The shapes of the letters appear to be cuneiform adaptations of the linear forms seen in the handful of contemporary or earlier inked or incised texts. However, they bear no relationship whatsoever to the signs of Mesopotamian cuneiform, which was in use at Ugarit for Akkadian, Hurrian, and, rarely, Sumerian (for the early epigraphic material, see Cross 1979, 1989). The Ugaritic documents include both ephemera and belletristic compositions. These two categories are also found in the rare surviving abjad-written items not impressed on clay tablets: ostraca, seals, and sealings. [*See* Seals.] Fifth-century BCE (and later) papyri from Egypt represent the more quotidian scribal output, while monumental inscriptions found from Dan to Beersheba (and well beyond) record, usually, the conquests and border claims of local rulers, and, especially in South Arabia, achievements in public works projects (such as irrigation systems) as well. The literary records of the Levant have not survived in contemporary manuscripts; the earliest biblical texts are among the Dead Sea Scrolls, and the Bible mentions a number of works that have vanished completely. From the first millennium CE, Syriac, Mandaic, and Jewish Aramaic incantations written on apotropaic bowls and on a handful of other items are preserved from Mesopotamia; the Cairo Geniza, from the end of that millennium, has yielded thousands of fragments of texts (both sacred and mundane) relating to the Jewish community there.

As Christianity spread to the north and east, scripture translations and a great literature were produced in Syriac. In the seventh century, the Prophet Muhammad dictated the Qur'an. Not long after, the Jewish Masoretes recognized the need to fix exactly the pronunciation of the Bible. For each language, a means was required to denote all the vowels in the sacred texts; in each case, the practical reason was different, but the solutions devised were similar. The resulting vowel pointings (not called matres lectionis) remain in use, yet optionally, to this day; theoretically, they change the *abjads* to alphabets, but their absence in the great majority of written materials shows that the supposed advantage of full explicitness of the alphabet is illusory.

Alphabet. The adoption of writing by the Greeks, with the accidental invention of the alphabet, has fallaciously been taken to mark the onset of "true literacy" in history; but this position derives more from ignorance of Near Eastern materials than from any facts of classical civilization (Peter T. Daniels in Daniels and Bright, 1996, sec. 2). It suffices here to outline the descent of the alphabets of Europe. The Greeks brought their script to their colonies, where it flourished and developed varieties (it was standardized in Athens in 401 BCE). A variety planted in Italy was taken up by the Etruscans, whose improvements were passed on to the Romans, resulting in the alphabet used throughout Western Europe and by its cultural descendants. Nonliterate peoples converted by missionaries from the western branch of Christianity tended to adopt the Roman alphabet, while those taught by Greek-speaking missionaries preferred to devise new scripts for their languages on the Greek model, notably Armenian, Georgian, and Glagolitic/Cyrillic (Daniels and Bright, 1996, pt. V).

Abugida. A handful of monumental inscriptions from early in the fourth century CE attest to the introduction, probably several centuries earlier, of consonantal writing from South Arabia to the kingdom of Axum, in present-day Ethiopia and Eritrea. Simultaneously with the conversion of the kingdom to Christianity in the year 348, the script became provided with vowel indications, in the form of appendages and modifications to the consonant letters. This technique cannot have come from Syrian missionaries because Syriac script then represented vowels only with matres; nor from Greek or Coptic missionaries, or vowels would presumably have been indicated with separate letters. Rather, there must have been some awareness, however ephemeral, of the scripts of India, perhaps mediated by the Martomite Christian community around Madras (Daniels, 1992a).

Paleography. While the use of a writing system (the principles of orthography) remain quite stable throughout its existence, it is readily apparent that handwriting changes across generations. The scribes of a particular time and place tend to form their characters in a similar way, if only so that each can read what the others write. Fashions in handwriting can often be correlated with aesthetic aspects of the surrounding culture—for example, the angular handwriting used where Gothic architecture included pointed arches, compared with the rounded writing popular along with Romanesque rounded arches.

The variation is usually not so spectacular. Subtle differences in handwriting between regions and generations make possible the craft of paleography. Given enough precisely dated and placed manuscripts, and intimate familiarity with

as large a corpus of materials as possible, a scholar can assign a given undated document to a limited area and a range of half a century or so. A particular scribe's handwriting is not likely to change over his or her career (Daniels, 1984), so that during any particular decade, or year, documents may be produced representing three or four generations of scribal training and fashion.

Hundreds of thousands of documents in cuneiform have been excavated from several millennia and throughout the Near East. Early in the course of Assyriology, massive collections of the data needed to establish cuneiform paleography were compiled, but no study has ever been completed of the handwriting practice of even a single scribal community. However, René Labat (1948) includes a wide selection of normalized forms of each sign used in Akkadian; and Robert D. Biggs (1973) begins to point the way to what is needed for every region and period before a useful cuneiform paleography can be produced.

Because the West Semitic materials are by comparison limited, it has been possible to draw up handbooks of paleography in several areas. Frank M. Cross (1961) deals with the scripts of the fourth century BCE to the first century CE, mainly as a help in the study of the Dead Sea Scrolls. Beatrice Gruendler (1993) gathers the materials relevant to the history of the Arabic script; Jacqueline Pirenne's 1963 study is the fullest of the Syriac; Alexander Klugkist (1986) covers Mandaic; and Solomon A. Birnbaum (1954–1971) deals with Hebrew to the twentieth century CE.

There are so few epigraphic monuments (Semitology, unlike classical studies, does not distinguish epigraphy, studying incised texts, from paleography, studying inked texts) from the first half of the first millennium BCE, and a little earlier, that every scholar can be expected to be familiar with the full range. As new texts are discovered, they are thoroughly analyzed, and incompatible conclusions regarding their place in the history of writing inevitably arise. The most notable recent example is the Aramaic–Assyrian bilingual from Fakhariyah, which comes from a place and time that makes it relevant to the discussion not just of West Semitic script history, but to the origin of the Greek alphabet as well. [*See* Fakhariyah Aramaic Inscription.]

PETER T. DANIELS

WRITING MATERIALS. If Paleolithic cave paintings are taken as the earliest records of human communication, it can be seen that notation began with mineral substances: cavern walls and ground-earth pigments. Vegetal and animal substances successively came into use.

Mineral Substances. The oldest surviving documents, the proto-cuneiform corpus from Uruk, are written on clay, "a natural, earthy, fine-grained material that develops plasticity when mixed with a limited amount of water" (Grim, 1979, p. 700), "formed by the decomposition of . . . rock-forming minerals, notably the feldspars"; they are "hydrated aluminium silicates with subordinate amounts of alkalis, alkaline earths, iron oxides, etc." (Scott, 1954, p. 379). [*See* Cuneiform; Uruk-Warka.] Clay used for cuneiform tablets (as opposed to pottery clay) has apparently never been physically analyzed; Denise Schmandt-Besserat (1992, p. 29) reports that the tokens used in preliterate accounting are most commonly made of a clay called montmorillonite (not mentioned by Grim, 1979). Lindsay Scott (1954, pp. 379–380) distinguishes primary from secondary clays. The former (bedded where they form, in marshes or bogs) include the kaolins or china clays; the latter (transported by water, wind, or ice from their primary source, acquiring additional impurities) are virtually ubiquitous, and it is these that seem to be used in cuneiform tablets. Mixed with an appropriate amount of water, clay is plastic; a mass of it suitable to accommodate the length of the text to be written would be modeled by a scribe into a shape dictated by tradition or convenience (usually a rectangular parallelopiped—called a tablet—for most uses; a disk for a practice text; or a hexagonal prism for annalistic texts). [*See* Tablet.] The obverse surface—the first to be inscribed—was flattened (Jerrold S. Cooper [1996, p. 38] claims that the flattening occurred when the tablet was set down on a flat surface for drying after the obverse was written, but is this not precluded by the high viscosity of the material?), the reverse being somewhat convex. Air drying was the normal way for inscribed objects to harden; very exceptionally, they could be baked, like pottery. Charles E. Jones (personal communication) observes that far fewer, if any, tablets were intentionally baked (as opposed to being accidentally cooked in conflagrations) in antiquity than is generally thought. Jones has also noted that at least some tablets have a mud core with a clay veneer to receive an inscription; and that when such a veneer chips off, pieces can be mistaken for fragments of clay envelopes. The India House Inscription (a very large slab inscribed on five sides recovered from Babylon at the beginning of the nineteenth century, one of the key documents used in the decipherment of cuneiform) seems to be hollow. [*See* Babylon.]

The wedge-shaped impressions that comprise cuneiform characters were made by lightly touching the surface of the clay tablet with a stylus (see below), or by stamping a complete commemorative inscription onto the faces of building bricks; clay is, thus, the primary medium in the Mesopotamian sphere. Mycenaean texts, in Linear A and Linear B, were also written on small clay tablets, but the characters were formed of incised lines rather than impressed wedges. Cuneiform (and other) writing could be imitated on non-yielding surfaces, including cliffsides, quarried or freestanding stones, or portable objects. Stone could be incised using mallet and chisel; the gypsum of which Mesopotamian palace reliefs were often fashioned is a very soft stone and easily worked, whereas boundary stones and other objects for unsheltered display needed to be more durable and must have presented a greater challenge to the engraver. The limestone of statues and other objects is of intermediate hardness. The Hammurabi stela, on which the wedges of the characters are outlined rather than hollowed out, is said to be of diorite. The Rosetta stone, originally described as basalt, is identified in a not-yet-published analysis as a form of granite. In Egypt, hieroglyphic inscriptions (originally written with a pen or brush, see below) could be carved at great length into limestone walls. [*See* Hieroglyphs.] Some monuments in various peripheral areas—among them some Luwian hieroglyphic and Aramaic and South Arabian consonantal inscriptions—exhibit characters that are not incised but are in relief, with the background cut away. [*See* Luwians; Aramaic; South Arabian.] Another material on which writing is sometimes incised is metal: a gold tablet of Ashurbanipal, bronze plates both at Byblos and in early Italy, a copper scroll from Qumran, strips of lead with Gnostic Mandaic inscriptions. [*See* Byblos; Copper Scroll; Mandaic.]

Naphtali Lewis's statement "The need to adapt the cuneiform script of the Fertile Crescent to the pen-and-ink technique of papyrus undoubtedly was a factor in the Phoenicians' development of the world's first alphabet" (1974, pp. 84–85) cannot be defended. [*See* Papyrus.] Assyrian scribes had no difficulty in imitating impressed wedges on a flat surface (see Baer, 1960). Conversely, the Northwest Semitic linear consonantary was successfully adapted to cuneiform technique at Ugarit. [*See* Ugarit.]

Writing also appears on pottery (baked clay): when a vessel shatters, no longer serving its original purpose, the sherds can be written on with ink—they are then called ostraca. Ostraca are often the only kind of ink inscription that man-

ages to survive the stresses of the physical environment; they have been found throughout the Fertile Crescent, from Aššur to Aswan. [*See* Ostracon; Aššur.] Examples of pottery created especially for the purpose of being written on are the apotropaic bowls of Jewish, pagan, and Mandaean tradition. They bear incantations written in a spiral on the bowl's inner surface and were buried upside down under the floors of houses to ward off demons, such as Lilith.

Such ink from the ancient world that has been analyzed generally proves to consist of carbon. Lampblack or incense soot was mixed with water and a small amount of gum arabic to produce a nonfading writing liquid. Iron-based black is not found until about the seventh century CE, and ink made from plant sources (e.g., oak galls) found later, in Europe, is not reported from the Near East. Rubrication could be done in red ink made with ocher, an iron-containing earth (Lucas, 1962, pp. 362–364).

Vegetal Substances. A blank roll of papyrus has been found in an Egyptian tomb at Saqqara dated to 3100 BCE (Černý, 1952, p. 11). [*See* Saqqara.] The Egyptians wrote on papyrus as long as their civilization endured; the earliest testimony to papyrus elsewhere in the ancient Near East comes from the Tale of Wenamun (c. 1100 BCE), but it must have been in use well before that. Only the exceptional desiccation of the Egyptian and Transjordanian deserts allowed the survival of papyrus over the millennia.) Papyrus was ubiquitous in classical Greece and Rome and spread with the expansion of the Roman Empire. The Merovingian chancery ceased using it in 677 CE, but elsewhere in France it continued for at least another century. Dated papyri come from Ravenna in 967, Spain in 1017, and the papal chancery in 1057; not until the twelfth century was papyrus completely superseded in Europe (Lewis, 1974, pp. 84–94).

Papyrus "paper" is formed from layers of the pith of *Cyperus papyrus,* a sedge that formerly grew to 3 meters high in marshy ground throughout the Nile Valley from the Delta as far south as Lake Tana in Kenya, as far west as Morocco, and north into Palestine. [*See* Delta.] In the Seleucid era it was introduced to Babylonia, and by the tenth century CE to Sicily (Lewis, 1974, pp. 3–20). [*See* Seleucids.] The chief, if not completely reliable, source for the preparation of the writing material is Pliny the Elder's *Natural History* (13.74–82). Fresh strips of pith were laid side by side on a flat surface, with their edges touching; more strips were laid on top of them, perpendicularly, again with their edges touching. They were then pressed together (and perhaps pounded with a mallet), and the plants' sap bonded them into a very smooth, white, flexible sheet that could be inscribed on both sides. Usually, the sheets were glued into rolls of twenty, with the horizontal fibers on the inside. The joins were nearly imperceptible, and when a scroll was written in columns, the column breaks did not need to correspond to the joins. [*See* Scroll.]

True paper is "a matted or felted sheet of fibres formed on a fine screen from a water suspension" (Tsien, 1985, p. 35). It was invented in China, perhaps around the beginning of the common era (rather than in the second century CE by Tshai Lun, the traditional account). The earliest such fibers

WRITING MATERIALS. *Three inkwells from Qumran.* (Courtesy ASOR Archives)

seem to have been silk, though paper-mulberry bark was used later. Only textile fibers were used outside China (not bark, and not, until the nineteenth century, wood pulp). The manufacture of paper was not a closely held secret monopoly of China, as is often stated. It was made in neighboring areas as soon as they came into contact with the Middle Kingdom. (The Qur'anic word *qirtas* is believed to be a Chinese loanword in Arabic.) Paper was manufactured in Muslim Samarkand from 751 onward, and in Baghdad by the end of the eighth century. [*See* Baghdad.] From there it spread to Damascus and across Africa in the ninth century; it was introduced from Africa separately to Spain and Italy in the twelfth and thirteenth centuries, and then spread across Europe (Tsien, 1985, pp. 296–303, citing and correcting Hunter, 1947). The oldest dated paper book in the West is a fragment of the *Thousand and One Nights* reused by a legal scribe in 879 (Oriental Institute, 1982, p. 130).

Writing implements fall under the heading of vegetal substances. Not surprisingly—because it is assumed that the stylus was made of wood or reed—no stylus used for impressing wedges on clay has ever been identified in excavations in Mesopotamia. The literature unanimously assumed that the stylus had to be cut to some angle in order to produce wedge-shaped impressions (Driver, 1976). H. W. F. Saggs (1981) plausibly suggests that a sedge widespread in Iraq, with a stem that is triangular in cross section (like the related papyrus plant), could be used to produce the needed shapes without modification beyond stripping off its leaves. (Unfortunately, he does not supply the botanical identification of the species.) This account also explains why the impressions are wedges rather than dots, rectangles, stars, or anything else—the script did not go through stages of experimentation as to suitable shapes of the components of the characters.

Robert M. Whiting (personal communication) has observed that wall paintings from Tell Barsip show the stylus held palm downward, passing under the palm at a low angle to the clay [*See* Til Barsip]; he has determined by microscopic observation that the stylus was rotated through 90 degrees to make horizontal and vertical wedges, noting that the stylus leaves a mark with one smooth side and one side that shows the grain. Horizontal wedges have the grain on the bottom, whereas vertical wedges have the grain on the left side. Thus, the stylus was held in the direction of the writing to make a horizontal wedge and perpendicular to the direction of writing to make a vertical wedge; in positioning the stylus to make wedges of different orientations, the scribe could rotate both the stylus and the medium (which was held in the other hand), to make them meet in the proper relative position.

The notion that the pens used to write Egyptian hieroglyphs were flat-tipped reeds chewed into brushes apparently goes no further back than an unsupported assertion by James H. Breasted of the University of Chicago in 1916. Rather, the sharpness of line even in very early papyri indicates that the pen differed little from that discernible in fifth-century BCE Aramaic papyri or that in current use: it was likely a hollow reed trimmed so that a shallow arch was what made contact with the writing surface, split for a centimeter or so to facilitate the flow of ink (Daniels, 1984).

Animal Substances. The transition to the category of animal substances is represented by wood tablets covered with beeswax that takes the wedge impression of the stylus. They are known from contemporary accounts, but very few have survived (Driver, 1976, pp. 225–226).

The three terms for prepared animal skins used as a writing ground—leather, parchment, and vellum—are not clearly differentiated. Driver (1957, pp. 1–3) apparently uses the word *leather* for any writing on skin, including parchment; Alfred Lucas and J. R. Harris discuss leather and parchment in separate sections (1962, pp. 33–37, 38–39); Dard Hunter (1947, pp. 13–16) distinguishes parchment and vellum by both animal of origin and technique of manufacture; and David Diringer (1953, p. 170) agrees with current usage in calling vellum merely "the finer quality" of parchment, "finer in grain, whiter, and smoother."

Egyptian leather was prepared by treating hides and skins with a number of different substances; true tanning (i.e., with substances containing tannin derived from acacia pods or oak bark) was known in Egypt in the predynastic period. Other materials used include ocherous earth, salt, fat, urine, dung, brain substance, and alum.

For Lucas and Harris (1962), parchment is prepared merely by "first removing the hair and then rubbing the skin smooth with some abrasive material, such as pumice stone." Other authorities insist that the preparation of parchment involves baths in lime (details in Saxl, 1956). For Hunter (1947), parchment is made from the inner layer of a split skin (the outer layer is used for leather), while vellum is made from the unsplit skin of a calf only. Thus, the two sides of the product differ—one being the hair and the other the flesh side. In gathering folded sheets into signatures for codices, care is taken to face hair side to hair side and flesh side to flesh side, to preserve the uniformity of appearance of each opening. [*See* Codex.]

It is difficult to date the earliest use of skin for writing. The "Driver letters" (1954, rev. ed., 1957), from the fifth century BCE, are the earliest surviving corpus, but scribes writing on flexible material—either papyrus or leather—are depicted in eighth-century BCE Assyrian reliefs. [*See* Assyrians.] The Akkadian textual evidence for leather and parchment is even later (Driver, 1976, pls. 23/2, 24; pp. 16–17, 228). By the time of the writing of the Dead Sea Scrolls, it seems that the preferred material for biblical texts was leather (as continues to be the case to this day for sacred Torah scrolls). [*See* Dead Sea Scrolls.]

It is often said that parchment replaced papyrus because papyrus is inferior in various ways (e.g., Diringer, 1953, p. 165). Lewis refutes this notion, attributing the gradual supersession of papyrus by parchment in the West (and by

paper in the East) to the diminution of the supply from Egypt, which was the result not of manipulation of the market or of withholding of the supply, but of the gradual draining of papyrus marshes for agriculture (Lewis, 1974, pp. 57–61; 1989, pp. 27–28). An advantage of both papyrus and parchment over paper is that they can be reused by washing or scraping off existing writing. Fortunately for later scholarship, the underwriting does not entirely disappear from such palimpsests. Many an otherwise lost ancient text has been partially preserved beneath a later text that to modern eyes is of less value.

PETER T. DANIELS

X

X-RAY DIFFRACTION ANALYSIS. The first step in identifying an unknown piece of matter is normally chemical analysis. However, this will mainly provide information on the elements present and not on how they are combined. If the material is crystalline (and almost all solids are, with the exception of glass), X-ray diffraction can supplement the information given by chemical analysis and indicate which compounds are present.

For X-ray diffraction measurements, the specimen is exposed to a beam of monochromatic X-rays (i.e., X-rays with a narrowly defined wavelength) and the intensity of the scattered radiation is monitored at various angles. Because the interatomic spacings in crystals are of the same order of magnitude as the wavelengths of X-rays, crystal structures behave as three-dimensional diffraction gratings for X-rays. A special property of such gratings is that the scattered radiation is reinforced at certain angles while it is extinguished at all others. Therefore, for a given wavelength (λ), appreciable scattered (or diffraction) intensities are only observed when the angle (Θ) satisfies the so-called Bragg condition, which is given by $n\lambda = 2d \sin\Theta$, where d is the spacing between the crystal lattice planes and n is an integer (i.e., 1, 2, 3, etc.).

The simplest technique for obtaining X-ray diffraction patterns is the powder method, which is the one most useful for archaeological specimens. A small sample, which can be less than 1 mg, is pulverized and inserted into a thin-walled glass capillary or deposited on a glass fiber. It is then mounted on the axis, which can be rotated, of a cylindrical X-ray camera, around whose interior a photographic film is wrapped. Because in a finely powdered and rotating sample the respective lattice planes exist at all orientations with respect to the incident beam, the Bragg condition is satisfied along the surface of a cone with a semiangle of 2Θ.

The spacings between crystal planes in a certain crystal system are characteristic parameters of each crystalline substance; it therefore follows that the diffraction pattern (i.e., the observed X-ray intensities at various angles) is also characteristic and can be used as a fingerprint to identify mineral phases by comparing them with cataloged patterns of pure substances. Mineral mixtures, of course, give mixed patterns, but mineral components of less than 10 percent are usually not detected. Thus, minerals can be identified even in mixtures; moreover, their relative amounts in the mixture can be estimated from the X-ray intensities. Only glass does not give any refraction pattern.

The major fields of application for X-ray diffraction analysis in archaeology are pottery analysis, to determine constituent minerals (clay, temper, decoration)—information often required to determine production techniques and provenance; identifying pigments in wall paintings and pottery decoration after firing; identifying corrosion products on the surface of metal objects for purposes of authentication; and identifying the microcrystalline structure of worked metals, which may reveal their mechanical and thermal pretreatment (e.g., if a wire has been drawn or rolled and hammered) as well as information concerning the development of metallurgy in ancient societies.

ERNST PERNICKA

Y

YABIS, WADI EL- (Ar., "dry valley"), perennial wadi located in northern Jordan, with a total catchment of almost 200 sq km (124 sq. mi.). The wadi descends westward a distance of 18 km (11 mi.) from the hills of Jebel 'Ajlun at 1,200 m above sea level, to the central Jordan Valley, which is 300 m below sea level. The great topographic and climatic range within this short distance results in a steep environmental gradient, with remnants of dense pine, oak, and pistachio forest at the highest elevations yielding to open scrub oak forest in the middle reaches and then to steppic grasses, weeds, and *Acacia st.* arboreal species in the valley. Tamarisk and oleander grow thickly along the banks of the wadi and the Jordan River. *Terra rossa* soils mantle the limestone highlands, while colluvial and alluvial soils accumulate on hill slopes and in wadi bottoms. Permanent springs are common along the eastern escarpment of the Jordan Valley, at the confluences of small tributaries, and at the headwaters of the Wadi el-Yabis catchment. [*See* Jordan Valley.]

The first Westerners to explore the antiquities of the region were early twentieth-century biblical geographers and classical art historian (Steuernagel, 1925, 1926; Augustinovič and Bagatti, 1952). In the 1940s, and again in the 1960s, the area was included in extensive surveys of northern Transjordan that identified the most prominent ancient tells (Glueck, 1951; Mittmann, 1970). The central Jordan Valley has been surveyed several times (Glueck, 1951; Mellaart, 1962; de Contenson, 1964; Ibrahim, Saner, and Yassine, 1976; Muheisen, 1988). Since the 1950s, limited excavations have been conducted at several valley sites near the wadi mouth, dating variously to the Lower Paleolithic (Huckriede, 1966; Muheisen, 1988), the Neolithic (Kirkbride, 1956), the Chalcolithic (de Contenson, 1960; Leonard, 1992), the Early Bronze Age (Fischer, 1991), and the Middle Bronze Age (Falconer and Magness-Gardiner, 1989). Between 1987 and 1992, a series of intensive archaeological surveys and test excavations was conducted throughout the wadi catchment (Mabry and Palumbo, 1988, 1992; Palumbo, Mabry, and Kuijt, 1990; Kuijt, Mabry, and Palumbo, 1991; Palumbo, 1992; Palumbo and Mabry, 1993). Almost 250 sites dating from Lower Paleolithic through Ottoman times were recorded within this area by 1992, and soundings had been excavated at six sites dating from the Kebaran period to the Iron Age.

The oldest clues of human use of the wadi are Lower Paleolithic handaxes, at least 100,000 years old, found at the edge of the Jordan Valley buried in wadi banks, cemented in limestone outcrops, and on the surface at flint quarries on the first ridges above the valley floor. Open-air and buried Middle Paleolithic sites are found at all elevations, but particularly on ridges near the valley, at the former margin of a lake that filled the central Jordan Rift during the late Pleistocene. Upper Paleolithic and Epipaleolithic sites are rare, but their presence attests to continued use of the wadi during the dramatic climatic fluctuations of the final Pleistocene.

In a cliff above the wadi, about halfway to the valley, a cave was inhabited by about 9200 BC, the beginning of both the Holocene and the early Pre-Pottery Neolithic (PPNA) period. A large (6 ha; 15 acres) village developed nearby between 8200 and 7000 BC, the late Pre-Pottery Neolithic (PPNB) period. Pottery Neolithic camps and villages were restricted to the valley. In addition to smaller settlements in the valley, large villages (up to 20 ha, or 49 acres) were occupied in the lower highlands during the Late Chalcolithic period (c. 4500–3500 BC). Extensive fields of piled stone tumuli and megalithic dolmens, both interpreted as tombs, are found in their vicinity and may date to that time.

At the beginning of the Early Bronze Age (c. 3500 BC), villages were established throughout the wadi highlands, implying extensive forest clearance for dry farming and herding. After 3000 BC many of these open villages developed into fortified towns, evenly spaced throughout the watershed to command roughly equal territories. Most of these were abandoned in the mid-third millennium and settlement dispersed into smaller villages and seasonal camps. Only the largest villages in the valley may have had protective enclosures during the Early Bronze IV (EB–MB) period (2400–2000 BC), a transitional interval between urban phases. A cemetery of rock-hewn EB shaft tombs covers an isolated ridge above the valley.

A new pattern again developed at the beginning of the Middle Bronze Age (c. 2000 BC), the start of the historic

record in this region, when settlements were reestablished at a number of abandoned protohistoric tells. Sedentary settlement in the wadi declined, however, during the later Middle and Late Bronze Ages. Rural villages flourished again throughout the region during the Iron Age (1200–586 BC), when the hillsides were first terraced for agriculture. A large fortified town developed at Tell Maqlub, which has been identified by some scholars as biblical Jabesh Gilead.

Only a few sites dating to the Persian and Hellenistic periods have yet been recognized, but this may be because of gaps in the ceramic chronology. Rural settlement greatly expanded during the Roman period though, when this region became a hinterland between the large urban centers at Pella in the Jordan Valley and Gerasa on the plateau. A road with mile markers was built to connect Pella, ʿAjlun, and Gerasa, crossing the Wadi el-Yabis near Tell Maqlub, and a second road was constructed along the eastern floor of the valley. Expansion of the areas of agricultural and pastoral production and timber harvesting for these urban centers led to rapid deforestation of the ʿAjlun highlands, and the resulting erosion led to the abandonment of some villages. This erosion was controlled by the intensive terracing of hillsides during the Byzantine period, when population and rural settlement in the area reached an all-time peak. On isolated hills, early Christian churches and monasteries were surrounded by their own terraced fields. In several still-occupied villages in the wadi, elaborate Byzantine mosaics are preserved in buildings that were once churches.

The Islamic conquest of Palestine was completed in AD 636 with the Arab defeat of the Byzantine army at the Yarmuk River, and the balanced relationships between urban, rural, and nomadic populations in the region were disrupted. A large number of settlements were abandoned during the period of Umayyad rule from Damascus. This decline accelerated after the ʿAbbasids moved the capital of the Arab Empire to Baghdad in AD 762, and the region became peripheral to major trade routes. Economic stagnation and village abandonment led to the neglect of agricultural terraces, resulting in another phase of soil erosion in the hills of Jebel ʿAjlun. During the twelfth century, the Jordan Valley was the frontier between areas controlled by European Christians and Arab Muslims, but the highlands of northern Jordan were protected by the Islamic fortress built at ʿAjlun.

After the Ayyubid general Salah edh-Din defeated the Crusaders at Ḥittin, near Lake Tiberias, in AD 1187, the region prospered as a result of its position between a united Egypt and Syria under the control of the Mamluks, a Turkish-Circassian military class. Many new settlements were established in the southern Levant, and the rural population of northern Jordan increased almost to the peak level of the Byzantine period. Along with the other major streams entering the Jordan Valley, Wadi el-Yabis was used to irrigate sugarcane plantations and to power mills processing the sugar for export.

After the beginning of Ottoman rule in 1516, repeated nomadic incursions into the cultivated lands of northern Jordan, along with the heavy taxation of the peasants, led to the abandonment of many villages. Only pockets of settlement remained in the highlands by the early nineteenth century, when the regions briefly returned to Egyptian control under the Balkan prince Muhammad ʿAli. Most of these remaining villages continued to be occupied into the twentieth century. Today, rapid population growth, intensifying land use, and illicit digging for antiquities increasingly impact the region's rich archaeological heritage.

[*Most of the sites mentioned are the subject of independent entries.*]

JONATHAN B. MABRY and GAETANO PALUMBO

YADIN, YIGAEL (1917–1984), Israeli military leader, archaeologist, and Dead Sea Scroll scholar. As an international figure and gifted public speaker, Yadin played a central role in creating the enormous popularity of and worldwide interest in the archaeology of Israel. He was also able to draw upon international sources of funding to undertake ambitious archaeological excavations and help establish such important archaeological institutions as the Shrine of the Book, which houses the seven complete scrolls from Qumran Cave 1 and the "Bar Kokhba Letters" at the Israel Museum, and the Institute of Archaeology at the Hebrew University of Jerusalem.

Born in Jerusalem in 1917, the eldest of three sons of Eleazar L. Sukenik, one of Palestine's first Jewish archaeologists, Yadin (known during his youth as Yigael Sukenik) studied archaeology at the Hebrew University. Although he spent most of the 1930s and 1940s in active service in the Zionist underground, the Haganah (in which he was given the biblical codename "Yadin" ("he will judge," from *Gn.* 49:16), which he later adopted as his surname), Yadin completed his master's degree in 1944 with a thesis on medieval Arabic inscriptions. He planned to write a doctoral dissertation on biblical weapons and warfare, but his full-time service in the 1948 Arab-Israeli war intervened. Named chief of operations of the Haganah (and, with the establishment of the State of Israel, of the Israel Defense Forces [IDF]), Yadin later served as IDF chief of staff (1949–1952).

Yadin resumed his archaeological career after retiring from military service and in 1955 completed his Ph.D. dissertation on the Qumran "Scroll of the War of the Sons of Light Against the Sons of Darkness." Almost immediately thereafter he joined the Hebrew University faculty and began excavations at Hazor, which continued until 1958. Yadin's directorship of the James A. de Rothschild Expedition to Hazor inaugurated a new era in Israeli archaeology. In uncovering vast expanses of Bronze and Iron Age Hazor, the expedition staff, guided by architect Immanuel Dunayevsky, developed a system of architectural stratigraphy that would long characterize the Israeli field approach. With regard to Hazor's biblical history, Yadin believed that the Late Bronze Age destruction levels provided conclusive evidence for a unified Israelite conquest of Canaan in about 1250 BCE. Later scholars would, however, question both the date and circumstances of that city's fall. [*See* Hazor; *and the biography of Dunayevsky.*]

Yadin's scholarly interests were wide ranging. In 1959 and 1960, he directed stratigraphic probes at Megiddo to test his hypothesis that the so-called Solomonic gates and later Israelite fortification systems were built according to uniform plans. He also devoted considerable attention to a study of the earthen ramparts of Middle Bronze Age Canaan, which he dated to the Middle Bronze IIB period (1850–1750 BCE) and attributed to the introduction of the battering ram by supposed Hyksos invaders. Yadin's great corpus of military artifacts and monuments, *The Art of Warfare in Biblical Lands in the Light of Archaeology*, was published in 1963.

In 1960, in response to reports of illegal digging in the caves in the Judean Wilderness, Yadin joined a large-scale expedition sponsored by the Israel Department of Antiquities, the Hebrew University, and the Israel Exploration Society. Yadin's sector included Naḥal Ḥever, where, in a large cave on the northern cliff face, he and his team uncovered a large collection of artifacts (including contemporary military dispatches and legal documents) left by refugees during the Bar Kokhba Revolt (132–135 CE). [*See* Judean Desert Caves; Bar Kokhba Revolt.]

Yadin's best-known excavation was at the mountain fortress of Masada (1963–1965). In addition to uncovering impressive Herodian palaces and administrative buildings, Yadin's team also retrieved written material, including hundreds of ostraca and several documents resembling those found at Qumran. Yadin gained great scholarly and popular attention with his assertion that the excavated human remains were those of Masada's last Jewish defenders, who, according to Josephus Flavius, had committed suicide in 74 CE rather than fall into Roman captivity. [*See* Masada.]

In the midst of the 1967 Arab-Israeli war, Yadin, then serving as security adviser to Prime Minister Levi Eshkol, obtained IDF assistance in confiscating and ultimately purchasing an important ancient scroll, discovered by bedouin in the Qumran region some years before, that had come into the hands of a Bethlehem antiquities dealer. Yadin's careful transcription of and exhaustive commentary on this document, which he named the Temple Scroll, focused the attention of scholars on the Qumran sect's religious law, or halakhah.

Yadin entered public life after the 1973 Arab-Israeli war, serving first as a member of the Agranat Commission investigating Israel's military preparedness for that war and later as the head of a new parliamentary list called the Democratic Movement for Change (DASH, its Hebrew acro-

nym). After serving as deputy prime minister in the government of Menachem Begin (1977–1981), Yadin returned to academic life. His last archaeological projects were a brief excavation at Tel Beth-Shean and plans to resume excavation at Hazor. With his death in 1984, traditional biblical archaeology, already under intellectual attack, lost one of its most eloquent spokesmen and influential practioners.

NEIL ASHER SILBERMAN

YAHUDIYEH, TELL EL-, site lying about 32 km (20 mi.) northeast of Cairo in Egypt's eastern Delta (30°17′ N, 31°20′ E), in pharaonic times Tell el-Yahudiyeh was in the thirteenth Lower Egyptian nome. Its Arabic name means "mound of the Jews"; this term alludes to the town and temple established at the site in the Ptolemaic period by the Jewish priest Onias. Its ancient Egyptian name was *Nay-tahut* or Nathō, and its Greek name was Leontopolis. Tell el-Yahudiyeh has been investigated half a dozen times over more than a century: the most important excavations were those conducted by Edouard Naville and Francis Llewellyn Griffith in 1887, and by W. M. Flinders Petrie in 1906. The site's archaeological fame derives from the discovery here of important Levantine remains of the Hyksos period (Manetho's fifteenth dynasty, 1648–1540 BCE).

Little is known about the early history of Tell el-Yahudiyeh. As with many Delta sites, most of the ancient settlement today lies beneath the high water table and therefore cannot be excavated, and the surface remains have been extensively looted and destroyed over the centuries. Human activity at the site in the third millennium BCE is indicated by some stone vessels, and scattered, unstratified objects (e.g., scarabs) and possibly some graves suggest occupation during the early second millennium.

The largest surviving structure at Tell el-Yahudiyeh—a roughly square earthwork rampart about 460 m (1,500 ft.) long on each outer face and having an external plastered glacis and rounded corners—may relate to the Hyksos period. Many archaeologists believe that this structure was a fortification erected by the Asiatic Hyksos rulers who controlled part of northern Egypt. Petrie specifically identified the enclosure as a "Hyksos camp," primarily because of its similarity to a number of Middle Bronze II–III enclosures in the Levant. He discovered a similar enclosure (undated and now destroyed) at Heliopolis. The interpretation of the Tell el-Yahudiyeh rampart as a defensive system is not assured, however, nor is its dating. Petrie reports that a building complex of Rameses III (c. 1184–1153) cut into it; if true, that would make the enclosure earlier than the reign of the twentieth-dynasty king.) Some scholars view the enclosure as the temenos wall of a temple complex, citing as a parallel a wall of the twenty-sixth dynasty at the Delta site of Mendes.

A series of generally poor, secondary burials inside and outside the enclosure probably belonged to Levantine pastoralists of the late thirteenth and fifteenth dynasties. Pottery, scarabs, and other finds from the graves link this material to Asiatic burials from such contemporaneous eastern Delta sites as Tell ed-Dabʿa and Tell el-Maskhuta. [*See* Dabʿa, Tell ed-; Maskhuta, Tell el-.] The ceramics include a distinctive type of pottery now known as Tell el-Yahudiyeh ware (see figure 1). This pottery, which occurs most commonly in the form of juglets decorated with incised and punctate geometric patterns containing a white chalky filling, appeared in Nubia, Egypt, Syria-Palestine, and Cyprus during the Second Intermediate period. Its initial region of production probably was northern Palestine; it later was manufactured in several areas around the eastern Mediterranean. The widespread distribution of this pottery reflects extensive commercial relations.

Knowledge of the site's history during the New Kingdom is uneven. Little is known about the place in the early New Kingdom: eighteenth dynasty (1550–1295) excavated remains include little more than some burials. More plentiful are finds of the nineteenth dynasty (1295–1186). These include the quartzite base of a unique temple gateway model inscribed with the name of Seti I, some large statues of Rameses II from a destroyed temple of that king, and a granite column inscribed with the name of Merneptah. The twentieth dynasty (1186–1069) has left the remains of a temple and associated palace complex of Rameses III as well as some graves. Probably deriving from the temple palace are a large number of polychrome, glazed faience tiles showing foreigners, plant and animal motifs, and the

YAHUDIYEH, TELL EL-. Figure 1. *Tell el-Yahudiyeh ware pottery fragment.* Found at the Nubian site of Buhen, New Kingdom period. (Courtesy University of Pennsylvania Museum, Philadelphia)

king's name; these tiles are now scattered around a number of museums.

The history of Tell el-Yahudiyeh is again poorly documented for the first half of the first millennium BCE. Several inscribed fragmentary stone monuments as well as some burials attest to activity of indeterminate extent during the Third Intermediate period (1069–656). The site is mentioned (as Nathū) in the Annals of the Assyrian king Ashurbanipal (668–627).

About 160 the Ptolemaic ruler Ptolemy VI Philometor granted permission to the Jewish priest Onias to build a temple and town at the site. The precise location of the temple, which is mentioned by the Jewish historian Flavius Josephus in his work *Jewish Antiquities,* is uncertain: it was Petrie's opinion that the temple lay outside the northeast wall of the so-called Hyksos camp. From the period of the temple come a series of tombs containing burial stelae inscribed with Greek and Semitic names. The temple apparently stood for slightly more than two centuries, eventually being closed by the Roman prefect, Lupus, in 71 CE.

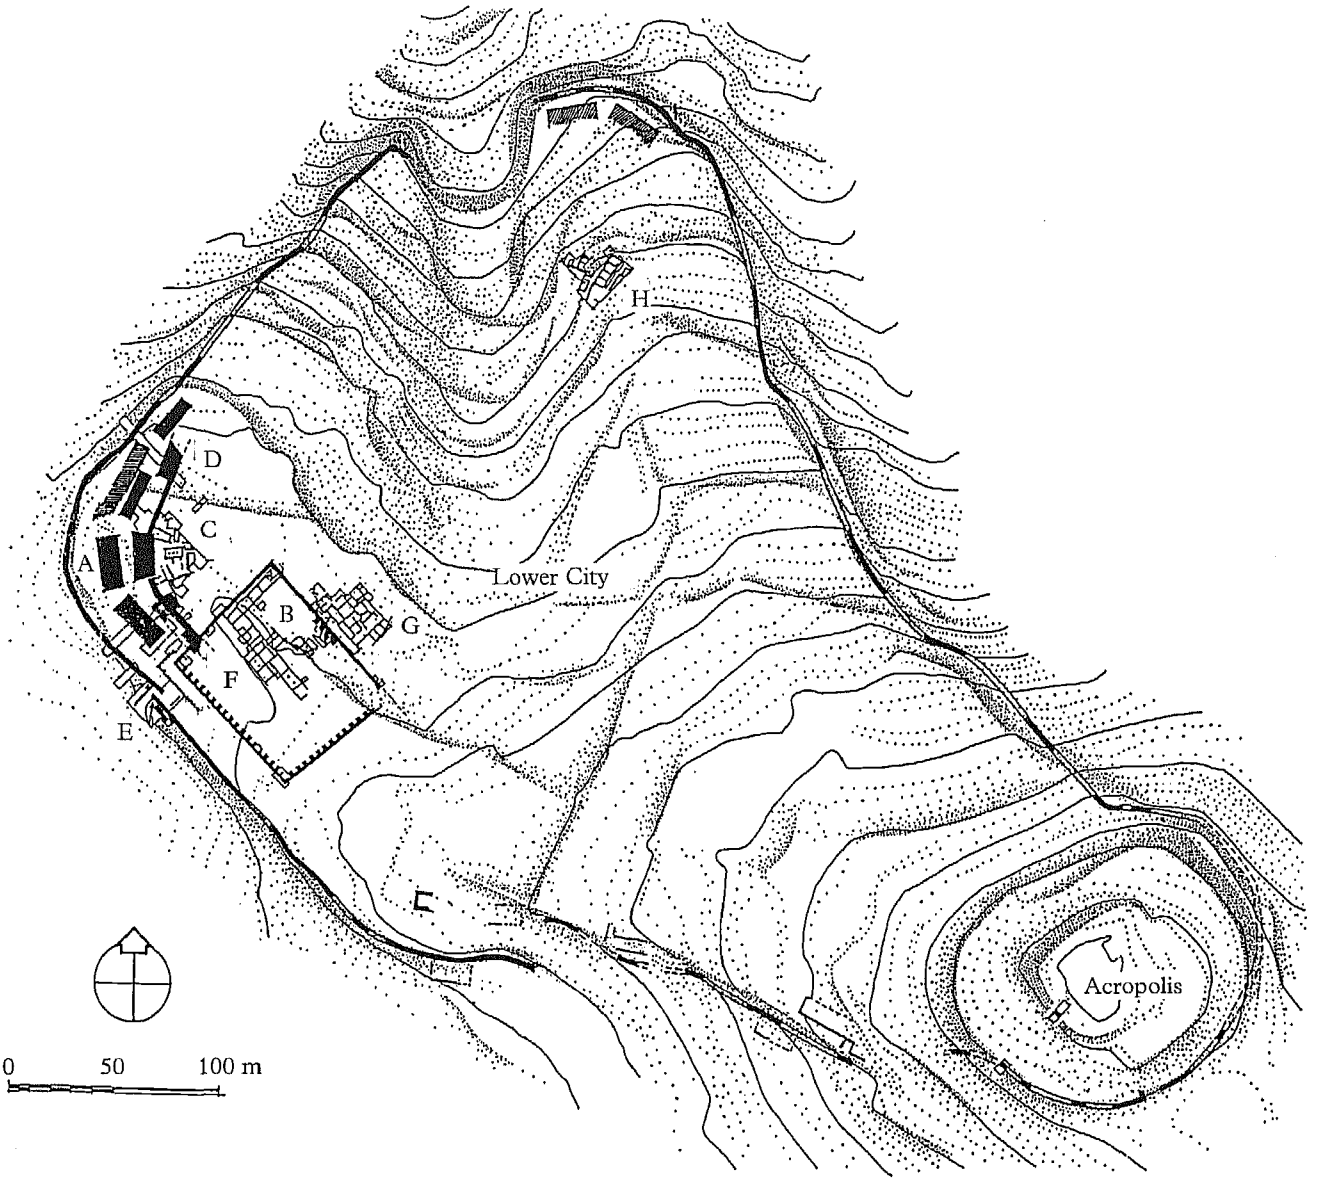
JAMES M. WEINSTEIN

YARMUT, TEL (Ar., Khirbet el-Yarmuk), site located in the central Shephelah, 25 km (15 mi.) southwest of Jerusalem (31°43′ N, 34°58′ E; map reference 147 × 124). The site is comprised of a small acropolis (about 1.5 ha, or 3.75 acres) and a large lower city (about 14.5 ha, or 36 acres), both of which were fortified in the Early Bronze Age (see figure 1). The site is about 640 m long and 420 m wide (about 16 ha, or 40 acres). The site is located on the slope of a hill, with the lowest point at 295 m above sea level and the highest point at 405 m above sea level.

The site may correspond to the "city of Yaramu" mentioned in a mid-fourteenth century BCE letter discovered at Tell el-Ḥesi (see the article by W. F. Albright in *BASOR* 87 [1942], p. 33). It is identified with the biblical city of Yarmut (*Jos.* 10:3–5, 23, 12:11, 15:35; *Neh.* 11:29), based on location, settlement history, and the continuity of its toponym: its Arabic name derives from Iermochos/Jermucha, a Byzantine village mentioned as being in this area by Eusebius of Caesarea (*Onomasticon* 106.24), who equated it with Iermous of the Septuagint, that is, biblical Yarmut.

Tel Yarmut was first settled in the EB I (second half of



YARMUT, TEL. Figure 1. *Plan of the site.* (Courtesy P. de Miroschedji)

the fourth millennium) and was inhabited until about 2300 BCE. It was not reoccupied until the Late Bronze II (c. 1400–1200 BCE). The resettlement took place only on the acropolis and in its immediate environs and lasted until the Early Byzantine period (fourth century CE). The major period of occupation (and the only one in the lower city) is thus the Early Bronze Age, when Tel Yarmut was one of the major fortified cities in Palestine.

Victor Guérin first described and identified the site in 1869, it was tested in 1970 by Amnon Ben-Tor on behalf of the Hebrew University of Jerusalem, and since 1980 it has been excavated by Pierre de Miroschedji for the Centre du Recherche Français de Jérusalem and the Hebrew University of Jerusalem, mostly in the west corner of the lower city. Excavation has revealed a remarkable EB fortified city, with monumental architecture on a scale unmatched at contemporary sites.

Early Bronze City. No remains of the earliest (EB I) occupation at the site have yet been found in situ in the lower city. By the end of the period, however, the settlement reached its west corner, presumably its full and maximum extent. By the beginning of the EB II, this area contained some large buildings, and, along the edge of the site, the first defenses appeared in the form of an earthen glacis. The construction of the first EB II city wall, which inaugurated a long sequence of fortifications, soon obliterated the glacis.

Fortifications. Three major EB phases and several subphases could be distinguished. The first EB II fortifications included a 5–6-meter-thick stone rampart and, in the corner of the city, a massive stone bastion (25 × 13 m). Two large rectangular buttresses were placed at equal distances from the bastion. At the end of EB II, a second city wall (3–3.6 m thick) was built with cyclopean stones. This additional wall made the city's defenses 40 m deep. The wall is preserved to almost 7 m in height in some places and can be traced all around the site for about 1.8 km (1 mi.). In the EB III, a series of very large defensive stone platforms (30–40 × 10–12 m), whose superstructure probably was brick, filled the west corner of the city.

Near the west corner a monumental offset gate was the single entryway into the second (outer) city wall. Preserved to a height of 7 m, access to it from outside the city was via an ascending U-shaped ramp flanked by retaining walls. At the end of EB III, the approach to the offset entryway was protected by a small rectangular "bastion."

Early Bronze II. Inside the city, only limited EB II architectural remains were excavated. A massive platformlike construction, earlier than the first city wall and apparently infrastructure, may have been the foundation of a civic building. A large structure, associated with the first city wall, and domestic buildings were also noted.

Early Bronze III. Most of the building remains excavated to date belong to the large EB III city, whose population may have reached three thousand. The inhabitants were mainly farmers who raised grains, vegetables, and grapes, and olives in abundance. They also practiced animal husbandry (sheep and goats primarily, but also cattle, which were used in the fields and for transport). The site's topography is characterized by a succession of large terraces with retaining walls that are several meters high. Its appearance may have resembled that of traditional villages seen in the region today.

Architecture. The city contained several public buildings. The so-called White Building was probably a sanctuary. It is a plastered, rectangular broadroom hall (13.5 × 6.75 m) with a central row of four columns and a main entrance centered in the southern facade. A chamber at its southeast corner, a courtyard in front of it, and two adjacent rooms to the south formed a complex interpreted as a sanctuary. Its plan resembles that of buildings of a cultic nature that belong to the Chalcolithic and EB I–III periods.

Even more impressive is a palatial complex in area B dated to EB IIIB (twenty-fifth–twenty-fourth centuries BCE). Measuring 84 × 72 m (about 6,000 sq m), it is by far the largest building complex known for the period in the Levant. It is demarcated by a thick wall with deep foundation trenches that is enhanced, for part of its length, with square inner buttresses placed at regular intervals.

While the southwestern half of the palace complex is occupied by a large courtyard, most of the northeast is covered with built-up areas. The complex comprises scores of corridors, small courtyards, and interconnected rooms, including several storerooms. Its construction techniques and quality, overall planning, and room layouts are strikingly different from contemporary buildings discovered so far at Tel Yarmut and elsewhere. Noteworthy is the systematic use of a cubit of about 52 cm, comparable to the Egyptian "royal" cubit. The complex's monumentality, together with the abundance of storage vessels recovered, clearly indicates its palatial function. Although this complex is reminiscent of building 3177 of Megiddo stratum XVI, it is still unique in the archaeology of third-millennium Palestine.

EB III domestic structures were extensively cleared in three areas of the lower city. Most interesting is area G, located on the northeastern side of the palatial complex, from which it is separated by a street. There, the private houses of stratum II were built on a series of small terraces and grouped in an insula bordered by a street. The typical dwelling was composed of one or two rooms (often with a central row of stone pillar bases), a courtyard with several domestic installations, and sometimes small storerooms. On the other side of the lower city, an area was identified in which nondomestic activities took place. Finds and installations (e.g., pithoi, large mortars, and ceramic vats in the floors) in a contiguous series of six small rooms and courtyards suggest that olive oil was processed in the area from the crop raised at the site.

Artifacts. Because it has the largest exposure of EB III remains in the region, Tel Yarmut is a type-site for this material culture in southern Palestine. It exhibits a complete corpus of the contemporary pottery, a large collection of human and animal figurines, and a variety of other objects in stone, bone, and terra cotta. There is evidence of "foreign" trade, with Egypt (stone palettes and fragments of vessels carved out of alabaster and diorite), as well as trade with northern and southern Palestine: sherds of rare Khirbet Kerak (Beth-Yerah) ware, worked basalt from the Golan, bitumen from the Dead Sea, and flint fan scrapers from the Negev desert.

Later Periods. By the twenty-fifth–twenty-fourth centuries BCE, Yarmut had reached the peak of its prosperity. Soon afterward the city was peacefully abandoned and remained deserted for about a millennium. Post-EB settlement was limited to the small acropolis. Excavations there have revealed traces of nearly continuous occupation from LB II to Early Byzantine times. The uppermost of the three Iron I strata appears to have been destroyed in a conflagration. It is dated to the mid-eleventh century BCE by its pottery, which resembles that found at Beth-Shemesh stratum III and Tell Qasile strata XI–X. On the northeast side of the acropolis the remains of a small Early Byzantine (c. fourth century CE) village that is to be identified with Iermochos in the *Onomasticon* (see above). Southwest of the acropolis and

on its slope, cisterns and rock-cut tombs were found that belonged either to the Byzantine or earlier periods.

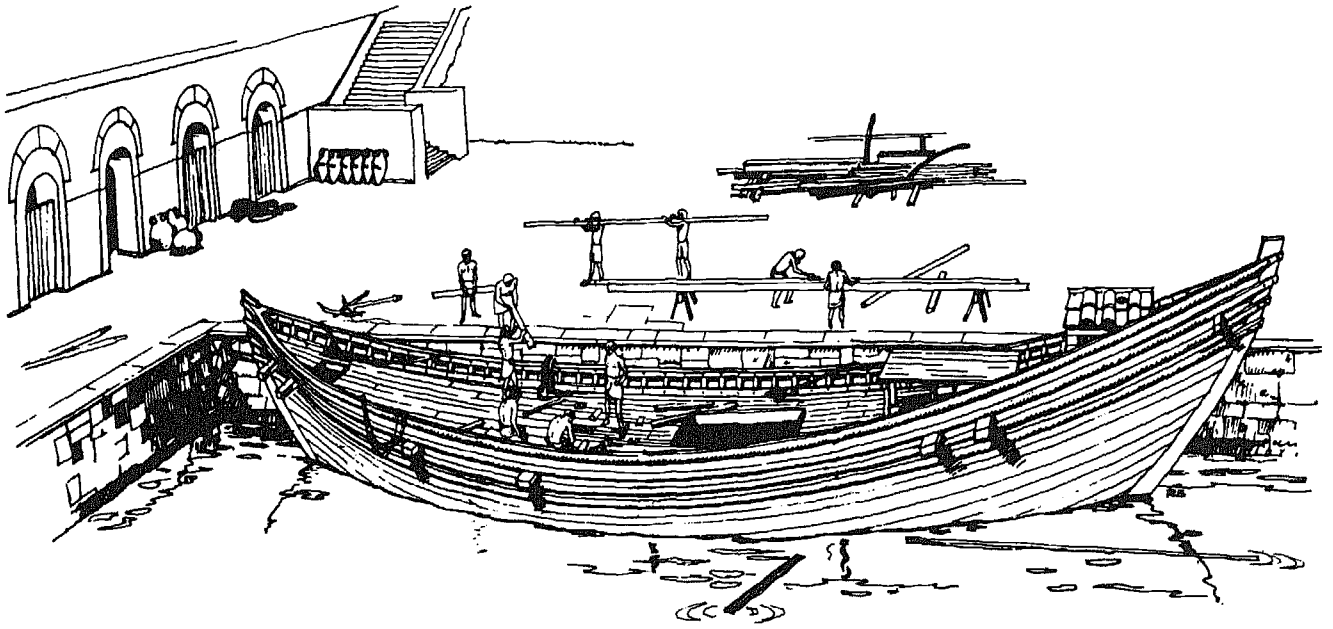
PIERRE DE MIROSCHEDJI

YASSIADA WRECKS. Yassıada (Tk., "flat island") is an island located between Turgut Reis, Turkey, and the Greek island of Pserimo; it is sometimes called Lodo (36°59′30″ N, 27°11′45″ E). The island is small, only 200 × 150 m, with a maximum elevation of 11 m. A reef that extends 200 m southwest from its southwest corner is especially treacherous, for it rises to within 2–3 m of the surface, about 125 m offshore. An unknown number of ships have run onto this reef and sunk, including a Lebanese freighter in 1993; cannonballs are mixed with amphoras on the reef top, with more coherent cargos of Roman-period amphoras and plates lying deeper on its sloping sides. Turkish sponge divers reported raising a ton of glass cullet from the northwest side of the reef in the 1950s, but other than a scatter of glass on that slope, there are no clues to its whereabouts.

At least three ships ripped their bottoms open on the reef, presumably while sailing before the northwest summer wind, and crossed over it to sink close to one another in deeper water off the island's south side. Reports of two of the wrecks by Turkish sponge diver Kemal Aras to Peter Throckmorton led the University Museum of the University of Pennsylvania to excavate one of them between 1961 and 1964.

A seventh-century Byzantine ship, lying at a depth of 32–39 m, approximately 75 m south of the island, it is dated to about 626 CE by fifty-four copper and sixteen gold coins found in its wreckage. Of 60 tons burden, about 20.5 m long, with a beam of 5.2 m, the ship was built in the ancient shell-first manner below the waterline; its pine planks are held together by loosely fitting and widely spaced mortise-and-tenon joints. Above the waterline, however, it was built in the modern frame-first manner, its planks nailed to the ship's elm frames (ribs) with iron nails. This provided the excavators with the first evidence that modern ship construction evolved, and was not an overnight invention. The keel, sternpost, and probably the stem were of cypress. A pair of iron bower anchors rested on either side of the bow, ready for use, with an additional seven iron anchors stacked just forward of the mast. The ship probably carried a single sail and seems to have been steered by sweeps that extended between through-beam extensions on either quarter of the hull. It carried in its hold a cargo of about one thousand wine amphoras in two basic shapes, globular and hourglass; they lack the knobs on their bottoms that had proved helpful in earlier periods for pouring. The disappearance of the knobs may have been the result of the invention of the "wine thief," a kind of pipette found on the wreck, which could draw liquid from a container without tipping it; the oldest known wine thief is from a wreck near Marzamemi, Sicily, from the sixth century.

The ship's stern galley, separated from the hold by a bulkhead, was roofed with terra-cotta tiles, one with a smoke hole over a tiled firebox that supported an iron grill. Virtually all of the personal possessions of those on board were stored here. In addition to the table and cooking wares, which comprise the largest well-dated collection of seventh-century ceramics, including the earliest-known Byzantine glazed pottery, were twenty-four terra-cotta lamps and various copper vessels. The ship's captain, owner, or merchant—or, perhaps, all three—was one Georgios Presbyteros Naukleros, whose name was inscribed on one of the ship's steelyards, the largest known from antiquity. It was he who must have carried a complete set of Byzantine weights, marked one pound, six ounces, three ounces, two ounces, and one ounce. The ship's carpenter stored his tools, the largest collection known from the seventh century, forward in the galley, whereas the boatswain's tools for gathering firewood and digging for water were in a separate storage area at the very stern, along with a grapnel for the ship's boat and net needles for mending fishing nets; that the crew fished is also indicated by lead sinkers. The finds suggest that the ship was sailing southward from a port on the Black Sea, or somewhere in the vicinity of Constantinople, on her last voyage.



YASSIADA WRECKS. *Drawing of the reconstructed Byzantine ship.* (Copyright INA)

Lying slightly deeper (36–42 m), about 100 m south of Yassiada, is a Late Roman wreck of the late fourth or early fifth century. It was partially excavated by the University Museum in 1967 and 1969. A later excavation in 1974, by the Institute of Nautical Archaeology, was halted by the outbreak of hostilities on Cyprus (Van Doorninck, 1976). The ship was 19 m long, with a length-to-beam ratio of 3:1. Its hull, mostly of cypress, but with a keel of white oak, was built in the shell-first Greco-Roman manner. Its pegged mortise-and-tenon joints were weaker and farther apart than those of most earlier vessels, however, although not so widely spaced as the unpegged joints of the later seventh-century ship (see above). These factors, and evidence for the early erection of half frames amidships to help the shipwright shape the hull, provide further proof of a slow evolution toward modern, frame-first construction. The ship's anchors have not been found. It carried about eleven hundred amphoras in its hold. The stern yielded Late Roman plates, a dish, a bowl, pitchers, a cup, cooking pots, and two large storage vessels; four terra-cotta lamps found there, of types made in the late fourth through early fifth centuries, one with the impressed signature of a known Athenian workshop that flourished at the time, provide the approximate date for the ship's sinking. Excavation deeper into the sloping seabed would surely reveal other artifacts that tumbled downslope as the ship disintegrated.

During the excavation of the second wreck, a previously unknown Ottoman hull that overlay part of it and nearly reached the seventh-century wreck was partly uncovered. The Institute of Nautical Archaeology, now affiliated with Texas A&M University, subsequently excavated it, under the direction of Cemal Pulak, in 1983. The ship was about 20 m long and built of oak. It was initially dated by a coin of Philip II to the sixteenth century. Its construction is now dated more precisely, by the dendrochronology of its keel, to sometime after 1572. It was almost barren of artifacts save for tools, glazed bowls like some from Çanakkale on the Asian side of the Dardanelles, lead shot, and both stone and cast-iron cannonballs (the last suggesting that this was a naval vessel, perhaps a supply ship, that was salvaged before being abandoned).

A Roman helmet of a type dated to the late third or second century BCE, found close to shore on the same side of the island, is matched by a helmet in Turkey's Bodrum Museum of Underwater Archaeology. A sponge diver brought the museum's helmet from an unknown location, very likely Yassiada, which is a site commonly worked by sponge divers. The two helmets suggest that a warship is hidden under the sand.

GEORGE F. BASS

YAVNEH-YAM (Ar., Minet Rubin), coastal site located 16 km (9 mi.) south of Tel Aviv–Jaffa (31°50′ N, 34°35′ E; map reference 1212 × 1479). The site was excavated for three seasons by Jacob Kaplan from 1967 to 1969, under the auspices of the Tel Aviv–Jaffa Municipal Museum. The Israel Antiquities Authority undertook a series of rescue excavations under the direction of Fanny Vitto (1980) and Yosef Levy (1987) in order to save a building complex from being eroded by the sea. Moshe Dothan (1952) suggests that Yavneh-Yam may be ancient Mᶜhôz, mentioned in the geographic lists of Thutmosis III and Alu-Muhazi in the Amarna letter no. 298. [*See* Amarna Tablets.] From Hellenistic times onward it is referred to as Jamnia (Iamnia). Arab geographers referred to it as Mahu Yubna. According to older views, a council of Jewish scholars completed the canon of the Hebrew Bible at Jamnia in 90 CE.

The site consists primarily of a square enclosure (approximately 800 sq m) bounded by a freestanding rampart. Based on the configuration of the ramparts at nearby Ashkelon, Israel Finkelstein (1992) suggests that the site may not have been enclosed on its western, seaward side. This would greatly reduce Kaplan's estimate of the site's size as 64 ha (160 acres). Kaplan was primarily interested in the rampart's construction and in fact found little evidence of occupation within the enclosure. He excavated two trenches, areas A and H, which cut across the rampart. The site dates to the beginning of the Middle Bronze IIA and continued in use intermittently through the Late Bronze I, when it was abandoned. It is possible that the site served as a harborage for the site of Yavneh 8 km (5 mi.) to the southeast.

In order to understand the rampart's construction, area A was cut from the top of the rampart down to its base. The sterile sand at the base of the rampart was leveled and covered with a thick layer of red clayey soil (Ar., *hamra*). The core of the rampart was a light-brown packed earth entirely covered with *hamra.* A glacis, composed of a layer of clayey soil covered by a layer of crushed *kurkar,* was then added to the rampart's exterior. In a later phase, this glacis was capped with stone to form a 30° angle. A series of three superimposed gates was found in area H, near the southeast corner of the rampart. The two earliest gates of strata III and II (MB II) were constructed of sun-dried mud bricks and flanked by towers. The LB stratum I gate was constructed of stone rubble. A second gate system was also detected along the eastern wall. Nine occupational layers on the inner rampart slope were excavated in area A. The earliest layer's ceramic horizon dates to MB IIA. Layers 8–3 date to MB IIB–C. LB I material, including Bichrome Ware, was found in layers 2 and 1. In area H, an MB IIA hearth was found on sterile soil in front of the stratum III gate. Fragments of ivory plaques were also associated with this hearth.

The site was reoccupied in the Persian period when it was probably a key administrative center. Based on the sherd scatter, the site expanded in the Persian and Hellenistic periods and was a large port in the Roman-Byzantine period. Judas Maccabaeus (Judah Maccabee) attacked Jamnia in order to destroy the Seleucid fleet (see Isaac, 1991, p. 140). A fragmentary Greek inscription on a limestone block, approximately dated to the reign of Antiochus V (164–162 BCE), is important for understanding the Phoenician influence on Jamnia. It appears that there was a strong Sidonian presence at the site beginning in the second century BCE. Vitto excavated the remains of a well-made polychromatic mosaic floor with a geometric decoration. [*See* Mosaics.] The floor was probably part of a large building complex that is dated to the Byzantine period. Levy excavated in this same area and found three Mamluk rooms with white mosaic floors and evidence of a wine press. Underneath the Byzantine and Mamluk mosaics earlier levels (Herodian, Hellenistic, and Persian) were found from which a Rhodian handle and a Hasmonean coin were recovered.

YEB. *See* Elephantine.

YEIVIN, SHMUEL (1896–1982), archaeologist, philologist, and first director of the Israel Department of Antiquities and Museums (1948). Born in Odessa (Ukraine) Yeivin immigrated to Palestine as a child and was educated in Tel Aviv. He served in the Turkish army in World War I and afterward studied Egyptology, Semitic philology, and Arabic at the University of London. During that period he had the unique opportunity to acquire considerable field experience on excavations in Palestine as well as in Egypt and Mesopotamia. Because of his philological expertise he was appointed chief translator for the British mandatory government in Palestine from 1944 to 1948.

Following the creation of the State of Israel in 1948, the country and Jerusalem, its capital, were divided. The Jewish state was suddenly detached from all Palestinian archaeological organizations, collections, and records libraries, including the Palestine Museum (now the Rockefeller Museum), which remained in the Jordanian sector of Jerusalem. Yeivin was assigned the task of creating a new archaeological service to deal with excavation and antiquities. He did so by creating the Israel Department of Antiquities and Museums (IDAM). Upon his retirement from the IDAM, Yeivin, with Yohanan Aharoni, founded the Institute of Archaeology at Tel Aviv University. Of the several excavations Yeivin conducted, the most important was at Tel 'Erani, which he identified with Gath of the Philistines, an identification no longer accepted. His work at 'Erani revealed an Early Bronze Age city, one of the major cities of the third millennium in the central part of the country. Unfortunately, he published only preliminary reports of that excavation.

RONNY REICH

YEMEN. An age-old cultural entity, *Yemen* potentially derived from the ancient designation *YMNT,* meaning the southern coastal region of present-day Yemen, which lay south of the ancient incense kingdoms ringing the Arabian desert during the first millennium BCE. In Islamic times the name signified a vaguely defined southern part of the Arabian Peninsula. A small group of Arab, European, and North American archaeologists and philologists have contributed to what is known of the history of Arabia Felix, as Yemen was called in antiquity.

Strategically located between Africa and Asia and geographically protected by both sea and desert frontiers, ports on the coasts of the Red Sea and the Indian Ocean complemented desert trade routes, giving direct access to the sources of frankincense (e.g., *Boswellia sacra,* from Dhofar and the eastern Ḥadhramaut) and myrrh (e.g., *Commiphora myrrha,* found as far west as Shabwa today) required for religious services throughout the ancient Near East and the Mediterranean. Volcanic glass, carnelian, and agate are found in Yemen; other stones and aromatics were imported (for reexport) from Africa and India. Although trade connections with the rest of the Near East have not been demonstrated before the tenth century BCE, the Egyptians may have regarded the land of Punt (a source of semiprecious stones and aromatics, with which they had been trading since the third millennium) as lying on both sides of the Red Sea; the land called Meluḫḫa in ancient Mesopotamia may, at times, have included Yemen. Camel caravans from the interior mountains crossed the edge of the desert, moving northward along the Red Sea coast to Petra, Gaza, and Alexandria, while seafarers traded with India and Africa. The Queen of Sheba (*1 Kgs.* 10:1–13) reputedly brought such objects, albeit incense is not specifically mentioned, to Jerusalem during the reign of King Solomon, but the significance of the text is controversial. Geographic isolation and excellent communications allowed a near monopoly on the aromatics trade, generating wealth through the first centuries CE, when Roman seaborne competition emerged. A decline in the demand for incense in the Mediterranean swiftly followed the advent of Christianity and the fall of Rome.

Geography. Tectonic crumpling on the southwestern edge of the Arabian shield produced the mountain ranges dominating the area between the desert and the sea. Volcanic activity on the desert rim ceased several millennia ago, but not in the central highlands, where a late first-millennium BCE site has been covered with lava. The monsoons break the mountains down, cutting gullies and passes, enabling communication, and rendering the land fertile, while filling the sails of trading vessels (the southwestern monsoon in fall, and the northeastern in spring). Wadis bring the water to both the sea and the desert; the erosion of the high western mountains (including the highest point on the Arabian Peninsula) creates the broad plains of the western Tihama (and covers historical-period archaeological sites un-

der meters of debris); and the lower southern ranges occasionally descend straight into the sea. Those wadis leading inland empty into the Ramlah al-Saba'tayn, a lobe of the Empty Quarter (the vast sea of sand dominating the southern center of the Arabian Peninsula, roughly between Najran and the United Arab Emirates).

Part of Wadi Jawf, which flows into the Ramlah al-Saba'tayn on the northeast, was the Minaean kingdom whose capital was at QRNW (modern Ma'in). YṬL (modern Baraqish) is on a plateau separating the Jawf from Wadi Dhanah with the Sabaean capital at Maryab (modern Marib). To the southeast lay the Qatabanian kingdom with its capital Timna' (modern Ḥayd Kuḥlan) at the mouth of Wadi Bayḥan. The roads to Marib led over the mountains across the virtually inaccessible Mablaqah Pass, or farther north on the edge of the desert through the Najd Marqad. Mountain ranges cut the Wadi Markha 'Awsan kingdom from Wadi Bayḥan to the west and from the desert to the north. Unlike the other kingdoms, Wadis Markha and Jawf each have several large mounds, and the capital of 'Awsan, MSWR, remains to be identified at one of the mounds in Markha.

In the early Holocene period, a river valley may have joined the Jawf across the Ramlah al-Saba'tayn with Wadi Ḥadhramaut to the east. In historical times, the capital of the Ḥadhramaut kingdom at ancient Shabwa was on the southern edge of the mouth. Wadi Masilah is the tail end of the wadi leading south to the Arabian Sea, but the main route joining the Ḥadhramaut with the sea follows Wadi Du'an (with the site of Raybun) up to the high plateau (the southern Jol) and down to the coast. The island of Socotra is 350 km off (217 mi.) the coast.

Prehistory and History. Artifacts show that parts of Yemen have been inhabited since the earliest Lower Paleolithic. Developed Oldowan material near the Bab al-Mandeb and in the Ḥadhramaut suggests that the Red Sea was crossed more than a million years ago, and that Yemen was first settled directly from Africa. Acheulean material is found sparsely throughout the confines of modern Yemen. Levallois and Mousterian of the Acheulean tradition are more common, using both locally available flint and quartzite. Upper Paleolithic blade cultures have so far been confirmed only in Wadi Du'an and on the northern edge of the Ḥadhramaut. Epipaleolithic artifacts are conspicuously absent.

Desert Neolithic (c. 6000–3000 BCE?) traditions using unifacially and bifacially retouched projectile points, as well as Rub al-Khali Neolithic tanged arrowheads, are found in the mountains and desert. Points indicate that hunter-gatherer economies corresponding to the Epipaleolithic continued to dominate in the desert, but in the Upland Neolithic tradition similar, albeit crudely executed, foliates are associated with circular and oval huts and incipient ovicaprid pastoralism.

The Bronze Age (c. 3000–1000 BCE) brought the expansion of animal husbandry and the introduction of pottery, polished stone tools, and the cultivation of cereals. Settlements (circular and oval huts and hearths) grew exponentially, so that the largest are more than 10,000 sq m, while others, fewer than 1000 sq m, became more numerous. Archaeological evidence of the earliest direct connections with northeast Africa, Mesopotamia, and India has not yet been found, but contacts must have existed, as indicated by the site of Ṣubr (just south of Lahej), with pottery similar to late third-early second-millennium BCE material from the north and east.

Toward the close of the Bronze Age, the South Arabian kingdoms (c. 1000 BCE–600 CE) arose on the desert fringe, each kingdom associated with an urban capital in each of the major wadis opening into the Ramlah al-Saba'tayn, just on the edge of the area where myrrh trees grow. In competition with one another, the kingdoms vied for political, economic, and military control of the trade routes. The chronology of the ancient incense kingdoms depends on some tenuous correlations, the most important identifying Karib'īl-Watar of Saba' (Sheba) who conquered the kingdom of 'Awsan as Karabilu the Sabaean who rendered tribute to Sennacherib of Assyria in about 685 BCE. An inscription referring to a war between Persia and Egypt cannot be placed later than the fourth century BCE.

After conquering 'Awsan (c. 700 BCE?) Saba' was dominant until Ma'in and Qataban became independent (c. 400 BCE). Competitive coexistence continued until Saba' and Ḥadhramaut swallowed them (first centuries CE). However, the Ḥimyarite mountain kingdom, with its capital at Ẓafar, progressively conquered Saba' and the Ḥadhramaut (third century CE) before the Ethiopians (with support from Byzantium) swept in (c. 525 CE). The Ḥimyarites subsequently brought in the Persians, who stayed put. Yemen was still under Persian rule at the adoption of Islam. The coastal ports changed their allegiances, as in the case of Qana' (Bir 'Ali), the port of the Ḥadhramaut, which must have replaced another port in the first century BCE and yet continued to flourish after Shabwa fell, until just before Islam.

The emergence of Islam coincided with the demise of the ancient kingdoms. The tribal components of the ancient kingdoms reasserted themselves, fragmenting the country's apparent unity. By the end of the tenth century CE, Yemen had become a theater in the confrontation between the various streams of Islam. Fatimid generals vied with insubordinate 'Abbasid vassals and rebellious Zaydi tribesmen for control of the mountainous highlands, while the Ayyubids finally imposed their rule before being eclipsed.

Ancient South Arabia. The people inhabiting these desert, mountain, and coastal regions seem to have identified themselves as a single cultural group, using the same system of writing and worshipping the same gods since the dawn of history. It would appear that the politicoreligious title *mukarrib* was only borne by one person in all of the South Arabian area at any one time, indicating a common identity despite political differences. The primary members of the

South Arabian pantheon were probably Venus (Athtar, a male: cf. Ishtar), the Moon, and the Sun, assigned different roles (and names) in the various kingdoms. Stone temple dedicatory inscriptions in monumental characters are among the most important South Arabic texts. Commercial transactions were recorded in a cursive script on palm sticks.

From the seventh century BCE, ancient South Arabian cities were generally surrounded by defensive walls, more commonly identified in the western than the eastern part of the country. Within the walls stood tall tower houses with rock foundations and superstructures of mud brick reinforced with wood (e.g., at Shabwa and Timnaʿ). South Arabian coins, bronze objects, stone incense burners, and pottery are the usual small finds. Most urban and town sites are laid out around large open areas, and with prominent sanctuaries, both intra- and extramural.

Prehistoric sanctuaries and cemeteries were frequently placed outside the associated settlement or along nomadic routes. The rectangular peristyle temples typical of Maʿin and Saba' reflect a more sophisticated form of the immediately preceding rectangular prehistoric temples and are found both intra- and extramurally. Some sanctuaries at Marib and Ṣirwaḥ are oval, while temples at Timnaʿ, Shabwa, and Raybun are rectangular hypostyle halls. Monumental temple porticoes are common throughout South Arabia.

Prehistoric cairns, dolmens, and stone alignments similar to monuments on the northern part of the peninsula are found frequently in the east but rarely in the west. In the historical periods, the rural dead were buried under cairns in a tradition going back to the Neolithic. The urban dead were also buried in silt accumulations (Saba' and Qataban) or in small chambers hewn into mountain rock (Qataban and Ḥadhramaut). Statues or stylized heads in stone boxes accompanied the weapons, jewelry, and other articles of daily use placed in the tombs. Ritual camel burials dating to the historical periods have been found in the south. The wealth of the tomb offerings was the result of trade. Constantly at odds, each of the desert kingdoms was nevertheless dependent on trade with its neighbors, as frankincense had to pass from Dhofar to the Ḥadhramaut, across the Ramlah al-Sabaʿtayn and on to Maʿin and the north, with the myrrh being passed on from Qataban and Saba'. The trading kingdoms were probably initially dependent on the camel, which requires little water, but much fodder, rendering agriculture the dominant activity in the historical periods.

The irrigation systems designed to catch and distribute the monsoon rains are among the most impressive South Arabian monuments. The original (second or third millennium BCE?) distributor structures in Marib were progressively updated and placed at more suitable locations until the ultimate dam (c. 500 BCE–600 CE) was built there, a masterpiece of engineering designed to contain the maximum amount of floodwater for distribution to more than 10,000 ha (24,700 acres) of cultivated land. Throughout Yemen ancient fields can be recognized by silt accumulations up to 30 meters high.

YIFTAḤEL, site located within a narrow valley, the southwestern extension of the Beth-Neṭofa valley in Lower Galilee (map reference 7086 × 6263). The site is sometimes identified with the biblical valley of Yiftaḥel (*Jos.* 19:14, 27), in references to the border between the territories of the tribes of Zebulon and Asher. This identification was recently extended to a small mound, Ḥorvat Yiftaḥel (Ar., Khirbet Khalladiyah). The designation is problematic, however, as the biblical account indicates a geographic feature rather than a settlement. The mound, located on the valley floor near a small perennial spring, was systematically excavated, but about 2400 sq. m. of late prehistoric occupation was exposed on the nearby east slope in salvage work directed by Eliot Braun for the Department of Antiquities and Museums of Israel.

Pre-Pottery Neolithic B (PPNB) Levels. Evidence of the earliest period of occupation at the site was confined to about 400 sq. m. in which a number of successive occupations were preserved. The major remains include rectangular, multiroomed dwellings, one of which had a central room flanked by two smaller chambers, sometimes interpreted as courtyards. Notable in this period are extremely well-preserved lime-plaster floors with rounded corners where they met the stone and mud-brick walls. A number of primary flexed inhumations were discovered beneath the floors of several houses.

Enormous quantities of flints, cores, debitage, and tools indicate the association of these earliest occupants of the site with the Pre-Pottery Neolithic B (Neolithic 2) culture of the southern Levant. A quantity of ground-stone tools, beads, bone tools, and some imported obsidian was also associated with these levels.

Charred horsebeans *(Vicia faba)* and lentils *(Lens culinaris Medik)* suggest a partially agriculturally based economy combined with hunting, especially of gazelle with some boar and wild goat. Although it is unusual for this period, there was no evidence of cereal farming or of sheep and goat husbandry as is often associated with contemporary occupations.

Stratum IV. Above the early PPNB levels and to the south, an occupation layer consisted of a number of long, meandering curvilinear or irregular fieldstone walls understood as segments of enclosures. Blocked doorways and superimposed, pebbled and earthen surfaces indicate internal phasing in this stratum. The associated flint-tool kit places it within the PPNB horizon. A large number of groundstone bowls, some fragmentary and built into the fabric of the walls, marks the layer's relationship to the succeeding stratum III occupation.

Stratum III. Extensively excavated, stratum III is notable for five rectangular fieldstone structures that share a north–south orientation, giving the overall impression of a well-ordered village. The most complete structure is a house with a porch and three rooms. The house is bisected by doorways along a single central axis. It belongs to a Neolithic tradition of pier houses that are typical of the PPNB in the southern Levant.

Superimposed floors, indicating several occupational phases, were primarily earthen or pebbled, but there was some evidence for the limited use of lime plaster. Several secondary inhumations were noted below the floors of houses and within the precincts of the adjacent courtyards.

To this stratum is attributed a large number of limestone bowls, hollowed from small and large stones from streams. These bowls are similar to those found in stratum IV. This levels' flint-tool kit also belongs to the PPNB period and can be characterized as a flake industry. Some of its typical prod-

ucts are naviform cores, ridge blades, adzes, axes, hammerstones, and arrowheads.

Below Stratum II. Evidence for the sporadic utilization of the site during the Late Neolithic (Neolithic 3–4) and Chalcolithic periods was recovered in fills and on occasional patches of surfaces encountered beneath the stratum II buildings. An identifiable small collection of artifacts includes typical Late Neolithic flint tools, pottery sherds of the Jericho IX and Wadi Rabbah horizons, and a basalt bowl decorated with incised triangles and vessels similar in shape to Neolithic pottery types but fashioned of lime, apparently a late manifestation of the *vaisselles blanches* tradition. A very schematic minuscule ceramic figurine, with enlarged proboscis, conical head, and ears only, either anthropomorphic or zoomorphic, apparently belongs to this horizon.

Stratum II. Remains of a densely occupied village of more than a score of curvilinear houses, may indicate a break with the rectilinear tradition that dominated domestic architecture from PPNB times to the end of the Chalcolithic period. These houses were found often directly on top of the stratum IV structures. Their stone foundations, varying greatly in size, were either circular (e.g., 4.5 m in diameter), oval (5–8 m long), or sausage-shaped (i.e., two parallel walls (12–16 m long) ended in an apse at both ends. Occasionally, the curved ends were paved with flat stones; the larger structures had curvilinear internal walls. These buildings are part of a short-lived but strong curvilinear architectural tradition that can be traced from Byblos in the north to Ashkelon in the south in the Byblian Chalcolithic and local Early Bronze I period (fourth millennium BCE). At Yiftaḥel, some slight evidence suggests as many as three phases within this period, but most of the haphazardly arranged buildings appear to have been contemporary.

This occupation's early EB I date is indicated by numerous examples of Gray Burnished ("Esdraelon") ware, as well as some typical vessels that continued Chalcolithic ceramic traditions but with such distinctive EB I features as indented ledge handles. The lack of grain-wash or band-slip decoration bolsters the argument for an early date within the EB I.

The flint-tool kit was primarily ad hoc, with Canaanean blades being extremely rare. The ground-stone assemblage included some typical finely worked EB I basalt bowls and a number of loaf-shaped basalt grinding stones. Two axheads and a delicate needle are the only copper finds.

Faunal remains suggest that sheep, goat, cattle, and swine were herded. The economy appears to have been somewhat mixed, with the addition of cereal production suggested by a number of flint blades bearing distinctive traces of sickle sheen.

Stratum I. A conglomeration of structures that were probably not all contemporary appears in stratum I. Two multichambered rectangular buildings with cobble pavements were devoid of finds and of uncertain date. Another enigmatic structure, a wide strip of fieldstones of varying widths, was found directly above several stratum II houses. Several poorly preserved walls and adjacent earthen surfaces were assignable, on the basis of typical pottery finds, to the Early Bronze IV and the Middle Bronze II–III horizons.

YIN'AM, TEL (Ar., Tell en-Na'am), an open-air site astride the Darb el-Hawarneh, the ancient road used as an international highway for trade and cultural diffusion from the Late Bronze Age until the early twentieth century CE to connect the Hauran in Syria with Akko in Palestine (32°43′ N, 35°3′ E; map reference 198 × 235). One of thirteen archaeological sites in a northwest–southeast-trending valley in the eastern Lower Galilee, Tel Yin'am is adjacent to Wadi Fajjas, near an inland branch of the Via Maris, at the eastern edge of an alluvial fan of basaltic soils that slopes from the Yavne'el scarp on the west side of the Yavne'el Valley. The site was occupied from the Yarmukian Neolithic until the Late Roman period. Although it is frequently identified with biblical Yavne'el/Jabneel (*Jos.* 19:33), it is not the only Iron Age site in the vicinity. Beth-Gan, which yielded transitional LB/Iron and Iron I material, is another candidate. [*See* Beth-Gan.] In the Jerusalem Talmud (*Meg.* 1:1, 70A) biblical

Yavne'el, a town at the southern border of the tribe of Naphtali, is identified with Khirbet Yamma, but no Iron Age material has been recovered from that nearby settlement. Early efforts to identify Tel Yin'am with Yeno'am in New Kingdom Egyptian sources are now generally disregarded. However, because the site yielded a significant LB II occupation and ended in a fiery destruction, its identification with Yeno'am, which some scholars believe to have been in the Bashan (Na'aman, 1977), may not be out of the question.

The site's rich alluvial soils and ample water supply from springs and wadis fostered an agriculturally based economy, but its inhabitants also engaged in trade and ironworking at the end of the Late Bronze Age. The site's location accounts for its trade connections and the variety and quality of its material culture.

The earliest exploration of the site was conducted by the Palestine Exploration Fund during the survey in western Palestine in 1873. Aape Saarisalo subsequently surveyed the site and carried out a sondage (which the present excavation identified by loose fill and a metal can in square K10 in the 1920s). He believed Tel Yin'am to be the key archaeological site in the valley and claimed that it had been occupied during the Bronze and Iron Ages and the Hellenistic, Roman, and Arab periods (Saarisalo, 1927). The site was later surveyed by Yohanan Aharoni and again by Ruth Amiran (Aharoni, 1957). The most recent survey, prior to systematic excavations, was conducted by Zvi Gal. His report (1992, p. 33) relied on the assessment of the site, as of 1981, by the University of Texas, which excavated there, under the direction of Harold Liebowitz, from 1976 to 1981 and 1983 to 1989.

In preparation for those excavations, Liebowitz conducted a sondage on the north side of the mound in 1975. Work was focused on the north and west sides of the mound (areas A and B). Area C, on the south side, which was badly eroded, was excavated for only one season. In 1978 a brief salvage dig was carried out 50 m west of the foot of the mound in area D, a terrace. The final seasons on excavation revised the site's occupational history. It is now known to have had fewer gaps in occupation than originally assumed. Its broad repertoire of pottery and small finds (see below) have helped to define the eastern lower Galilee as a distinct region in the Late Bronze Age, heretofore considered to have been basically unoccupied in that period.

Neolithic and Chalcolithic Periods. While the material evidence attests to the occupation of the site in the Neolithic and Chalcolithic periods, these levels were not reached in excavation because of the compaction of the soil below the EB I layers. The Neolithic pottery closely parallels assemblages from other Yarmukian sites (Stekelis, 1972), and the serrated flint blades recall sickle blades known from numerous Neolithic sites. The Chalcolithic period is attested primarily by large basalt hammers.

Bronze Age. The Early Bronze Age IA is best represented in area D (10 × 10 sq m), excavated on the terrace settlement (see above). There, a circular platform identified as a *bāmâ* was found in association with partially preserved walls. The surface of the area was 10 cm thick and produced a rich, densely packed assemblage of EB IA pottery paralleled at Khirbet Kerak (and some Neolithic pottery), a miniature basalt bowl, a rare ceramic bull protome, and a profusion of animal bones. A less significant EB layer was excavated on the west side of the mound.

The Middle Bronze Age is represented by the southwest corner of an MB fortress temple in a poorly preserved area immediately below the earliest phase of an LB II building in area B. The surface patch yielded an almost intact electrum figurine of a standing goddess that has parallels in silver from a temple at Nahariyah in Israel and at Syrian sites; and a flat, copper/bronze standing figurine with parallels at Byblos. These figurines from Tel Yin'am were found in association with an MB II cooking pot and the upper part of a large, unusual jar with plastic and incised decoration. The northern part of the structure had been bulldozed by a local farmer prior to excavation; its southeastern part remains unexcavated. Other MB II sherds were found in fills elsewhere in area B.

The tell was abandoned until the latter part of the Late Bronze Age. A ten-room central building (building 1) that served as the residence of the local ruler existed throughout the LB occupation and yielded finds including cylinder seals, a stamp seal, a necklace with a chalcedony lion pendant, and beads (including two gray-and-white barrel-shaped beads), two Egyptian heart amulets, a bronze plow point, an "Egyptian Blue" shallow bowl, basalt bowls, and millstones. [*See* Seals.]

Additional thirteenth-century buildings abutted building 1; all experienced two phases of occupation. On the cobbled floor of the storeroom of building 2 from the later phase, a dense concentration of sherds was found from which unusually large biconical jugs, store jars, and an unparalleled Mycenaean stirrup jar were restored, substantiating, along with the small finds (see above), the extent of foreign trade in the Late Bronze Age. The floor of building 7 was paved with meter-long flagstones. A 50-cm deep layer of ash, charred wood, fire-cracked rock, and burnt and disintegrated mud brick found on the floors of the major LB buildings was evidence of their violent end. In the final LB phase, room 1 of building 1 was turned into an industrial installation that apparently was a primitive iron smelter, heralding the coming of the Iron Age (see below).

Iron Age. The reuse in some places of LB walls in the Iron I settlements and floors laid directly above the LB destruction debris suggest that a relatively short period elapsed between destruction and resettlement. The Iron I buildings were sturdily built, and the pottery was of consistently high

quality. Though much of the western slope of the mound is eroded, and a significant portion of the Iron I levels was destroyed, the preserved remains attest that the site was continuously occupied throughout the Iron I and into Iron II A (the tenth century BCE).

The courtyard of one of two tenth-century (Iron IIA) domestic buildings in area B yielded an oil press, an olive-cracking installation, stone weights, and olive pits, suggesting the existence of a home industry. [*See* Olives.] A long room north of the courtyard yielded forty-five loom weights. Unusual small finds include a rare bimetallic knife and a cone-shaped seal that features two rampant longhorns, each with a human figure seated on its back. Only two loci produced rich assemblages of Iron IIC ceramic remains in situ on the mound, although large quantities of sherds were found scattered throughout the area. A homogeneous assemblages of Iron IIC cooking pots, jugs, and store jars was restored from a courtyard and a partially excavated building in area B. Building activity in the Persian period had considerably disrupted remains in that level.

Persian–Roman Periods. Evidence of a Persian period occupation at the site was found in two phases in areas A and B. The ceramic assemblages reflect local and imported wares, including bowls, jugs, juglets, store jars, cooking pots, and a large pilgrim flask; among the imports were an East Greek painted jug and Attic sherds. The period's most substantial remains were recovered in area B on the tell: a partially excavated building with walls one meter wide and a large stepped podium with a flagsone walkway leading to it. In area A a building with ovens and grain silos, whose dimensions suggest domestic use, was excavated. The site yielded no evidence of occupation in the Hellenistic period but was reoccupied in the Roman period. The domestic structures were comprised of two rooms and appear to have been small. The one exception is a building in area A, on the north. It was partially excavated along with Roman-period buildings in area B. There, because the mound sloped sharply, the western continuation of the walls and floors of several rooms was eroded. Unique to area C are the limestone ashlars used in the building that housed a six-stepped, plaster-lined *miqveh*. [*See* Ritual Baths.] Though carbon-14 tests conducted on the plaster from the *miqveh*'s walls suggest a sixth-century date, the pottery is Late Roman. The absence of Byzantine and Arab pottery either in Gal's survey or in excavation leads to the conclusion that the site was abandoned at some time prior to the fourth century.

YODEFAT. *See* Jotapata.

YOQNEʿAM, site situated at the northern outlet of Wadi el-Malih into the Jezreel Valley, at the eastern foot of Mt. Carmel (map reference 1604 × 2289). The site covers an area of 10 acres. Rising steeply above the surrounding valley, Yoqneʿam's location commands the vital junction of the route through the Malih Valley that connects the Via Maris of the coastal plain with the route across the Jezreel Valley that leads to the Plain of Akko and beyond, to Phoenicia. Its strategic position accounts for its long occupational history, from the Early Bronze Age to the Mamluk period. Egyptian, biblical, Byzantine, and medieval references to the site, including topographical data, and the resemblance of its Arabic name, Tell-Qeimun, to ancient Yoqneʿam, made its identification certain. Yoqneʿam enjoys exceptionally favorable environmental conditions: moderate climate, fertile soil, and an abundance of water.

Exploration. The site was first surveyed by the Palestine Exploration Fund in the late nineteenth century. In the early 1970s it was resurveyed by the Israel Survey. Excavations began in 1977 as part of the Yoqneʿam Regional Project, carried out on behalf of the Institute of Archaeology of the Hebrew University of Jerusalem, under the direction of Amnon Ben-Tor, and continued for ten seasons until 1988.

History. The earliest reference to Yoqneʿam is on an inscription at Karnak in Egypt that records a military campaign into Canaan by Thutmosis III (c. 1468 BCE). Yoqneʿam (the Egyptian rendering is *ʿnqnʿam*, probably referring to the springs at the foot of the site) is site number

113 on that list. The site is mentioned three times in the *Book of Joshua:* its king is listed as one of the thirty-one kings Joshua defeated (12:22); "the river that is before Jokneam" is the border of the territory of the tribe of Zebulon (19:11); and as a Levitical city within Zebulon's territory (21:34). Kammuna, in Eusebius's *Onomasticon* (116, 21), six miles from Legio, on the road to Ptolemais (Akko), is probably to be identified with Yoqne'am. The most frequent references to the site, under the name Caymont, or Mons Cain (both deriving from a tradition identifying it with the place where Cain was killed by Lamech) are to be found in Crusader documents. After the conquest of Baldwin I, it became first a royal castle and somewhat later the center of a small lordship. After their victory in the battle of Ḥattin (1187), the Muslims held the site for a short time, during which it appears in sources as al-Qaimun (Yaqūt 4.218). During the next century it changed hands several times. The site is last mentioned in a Frankish-Mamluk treaty dated 1268, in which al-Qaimun is listed among the possessions of the sultan Qalawun. The monumental structure covering the site's entire acropolis has been identified with the caravanserai built in the mid-eighteenth century CE by Dahir al-Omar, ruler of the Galilee. Whether it is indeed, or whether the remains belong to the site's Crusader fortress, will be decided by the brief rescue excavation currently in progress by the Israel Antiquities Authority.

Excavation. Five areas (A–E) were opened at the site and twenty-three occupation levels identified.

Early Bronze–Middle Bronze I (strata XXVII–XXIV). No in situ remains were found of any periods because in the areas excavated, subsequent builders, by founding their structures on bedrock, removed all previous architectural remains. However, sherds from all the site's occupational periods, including Gray-Burnished, Abydos, and Khirbet Kerak wares, as well as reserve-slipped Syrian sherds, were found, and stratum numbers were assigned for future reference.

Middle Bronze Age IIA–B (strata XXIIIA–C, XXII). Three interconnected rock-cut, bell-shaped burial caves constitute the earliest and only in situ remains at Yoqne'am. In one of them were two skeletons placed in arcosolia. The pottery associated with these burials dates them to MB IIA. The entrance to one of the caves was sealed by the site's earliest defense system: a solid mud-brick wall and a glacis. The two phases of these fortifications are dated within MB IIA. Another wall, not as wide as the former, and an associated tower, built on top of the fortifications, are dated to MB IIB. Little is known about the settlement's interior.

Transitional Middle Bronze IIC–Late Bronze I (stratum XXIA–B). The remains of dwellings built over the MB IIA–B defenses indicate an unfortified settlement. It is characterized by a large number of infant jar burials dated to the seventeenth–sixteenth centuries BCE.

Late Bronze Age II (strata XXA–B, XIXA–B). Four phases of an unfortified LB II settlement were discerned. The last of these had been violently destroyed, as indicated by a level of burnt debris more than 1 m thick covering all the remains. The date of that destruction should be placed somewhere in the late thirteenth–early twelfth centuries BCE.

Iron Age I (strata XVIIIA–B, XVII). After an apparently short occupational gap, the site was resettled in the Iron Age. Three architectural phases could be clearly discerned. The main architectural feature of the last phase is a house containing installations for the production of olive oil. Large amounts of pottery, both local and Phoenician or Philistine related, characterize this phase. The final destruction of the Iron I settlement may be related to the conquest of the Jezreel Valley by King David.

Iron Age II–III (strata XVI–XI). After a brief transitional phase, Yoqne'am was once again fortified. In the mid-tenth century BCE the city was surrounded by a massive casemate wall. A shaft cut into bedrock, whose excavation was not completed, probably led to the spring at the foot of the tell. The casemate wall was replaced in the ninth century by a defensive system consisting of two parallel walls. A peripheral street ran along the inner wall, separating the defenses from the city's residential buildings. These defenses went out of use in the late eighth century BCE, probably as a result of the Assyrian conquest of northern Israel.

Persian period (strata X–VIII). Three phases of an unwalled settlement from the Persian period were unearthed.

YOQNE'AM. *Iron Age double city walls.* Ninth century BCE. (Courtesy A. Ben-Tor)

YOQNE'AM. *Iron Age faience head.* Ninth-eighth century BCE. (Courtesy A. Ben-Tor)

A strong Phoenician influence is clearly indicated in the architecture and the ceramic finds.

Hellenistic, Late Roman, and Byzantine periods (strata VII–V). A watchtower from the Hellenistic period and a mausoleum from the Late Roman period are all that remain of the later periods of occupation on the tell. The main settlement appears to have moved to the hill immediately to the south. This may have been the case also in the Byzantine period. However, remnants of a church located immediately under the Crusader church on the eastern slope of the acropolis indicate a Byzantine presence at Yoqne'am.

Early Arab period (stratum IVA–C). A well-planned settlement was found that apparently extended over the entire surface of the site during the Early Arab period. It is dated by finds whose origins are local as well as Syrian and Egyptian and belong to the eighth–mid-tenth centuries CE.

Crusader period (stratum IIIA–B). After an occupational gap of about two centuries, Yoqne'am was rebuilt by the Crusaders. A residential quarter, a defensive wall, and a church are the main architectural features uncovered. There are clear indications of a massive fort having been constructed on the acropolis in this period, however.

Mamluk period (stratum II). Sporadic settlement occurred in the ruined Crusader city in the fourteenth century. It was confined mainly to the southern part of the site.

Ottoman period (stratum I). A few sherds and one tomb represent occupation during the Ottoman period (sixteenth-twentieth centuries). Some building activity may have taken place in the ruined Crusader fort on the acropolis.

Z

ZABID, site located centrally across the 50-km wide coastal plain of the Tihama, in the Republic of Yemen (14°12′ N, 43°19′ E). Founded in 820 CE (AH 203) and now a seat of local government, Zabid's medieval prosperity was the result of irrigable land watered by seasonal floods, good ground water, access to the Red Sea, and ease of ground communication along the pilgrimmage routes to Mecca.

Mention of the city's walls and four gates appears in the commentaries of 'Umarah al-Yamani (twelfth century) and al-Khazrajī (fifteenth century). The walls also are emphasized in Ibn al-Mujawir's thirteenth-century map of the city: it shows a concentric wall system, with varying dimensions attributed to different dynasties. Curiously, the city wall with largest circumference is ascribed to the little-known and rather weak eleventh-century Najahid dynasty of Yemen. There has been a tendency for modern commentators to assume that Zabid's standing gates reflect the medieval configuration of the city (see Chelhod, 1978). Surveys by the Canadian Archaeological Mission of the Royal Ontario Museum, directed by E. J. Keall, indicate that the modern gates have no great antiquity (Keall, 1984). In his unpublished diary Glaser located the pre-Islamic city on a map at a point 10 km (6 mi.) north of modern Zabid (see map reproduced in Pauly-Wissova, 1968, p. 1315). From the study of sherds found on a large site north of Zabid, the mission's finds lend credence to Glaser's otherwise unsubstantiated observation (see Keall, 1983). This site may date back to the second millennium BCE.

Beginning in 1982, the Canadian mission, guided by 1:50,000 maps, surveyed Zabid and its surrounding area. All of the sites found were Islamic, with the exception of the one north of Zabid and another found in a range of dunes close to the coast. Imported Chinese wares furnish vital dates from the tenth to nineteenth centuries. Apart from them, almost all of the pottery is unique to the project: it appears to have little in common with the ceramic finds from the Saudi littoral or the Egyptian Red Sea coast. Petrographic analysis has characterized local production and confirmed the identity of the Islamic imports (mostly from Iraq and Iran).

In 1987, the Canadian mission designed an excavation program to define the development of the city (see Keall, 1989, 1991). The strata were found to have been badly disturbed by intrusive pits. Extensive damage had been caused by brick robbers who had trenched along wall lines to remove baked bricks. Traces of the original walls were positively revealed by the cobblestone footings that, lacking recyclable value for the robbers, had been left. It has been possible to identify occupation from the ninth century CE to the present. The perimeter wall of the Zabid citadel is a makeshift arrangement from around 1904. A fort was first built there during the sixteenth-century Ottoman occupation.

Outside the citadel, traces of copperworking have been tentatively associated with coin production. The implication is that the area was always a government quarter. At a site farther south, the remnants of fourteenth–fifteenth-century domestic buildings were buried beneath the berm of a moat—a clear indication that the last surviving city wall was a moderately recent one. East of Zabid, a ninth–tenth-century workshop produced pottery greatly influenced by contemporaneous Iraqi styles. The clay source was wadi alluvium, which the potter had collected by diverting flood water onto the site in settling ponds.

North of the city, excavations unearthed a sequence of buildings, though only sparse floors and foundation trenches survived the brick robbers. Fragments of carved and painted plaster reflect the quality of the structures, which may have been suburban villas set among watered gardens. The sandy conditions prevalent at all stages reflect an environment little different from today's. Provisions for watering the gardens are indicated by the kind of underground pipes the project unearthed. Two sets of glazed earthenware pipes were found outside of Zabid, as well as a covered conduit that comes from the direction of the mountains (see Hehmeyer, 1995).

ẒAFAR, capital of the South Arabian kingdom of Ḥimyar, located approximately 8 km (5 mi.) south-southeast of the modern Yemeni town of Yarim and approximately 8 km east of the San'a-Taiz-Aden highway (14°13′ N, 44°24′ E). It sits at the eastern edge of an extensive intermontane valley near the head of Wadi Bana. Its identity has been known locally since antiquity and is confirmed by Ḥimyarite inscriptions found at the site.

Ẓafar, the Sapphar or Tapharon of classical authors, may have been founded as early as about 115 BCE, the beginning of the Ḥimyarite dating system. It was certainly in existence by the mid-first century CE, when it was mentioned by Pliny (*Nat. Hist.* 6.26.104 and by the unknown author of the *Periplus of the Erythrean Sea* (22–23). The earliest inscriptional evidence for Ẓafar consists of the Ḥimyarite royal titulary, "king of Saba and lord of Raydan," which occurs as early as the mid-first century. Raydan is generally understood to be the royal palace at Ẓafar.

Early explorers of the area include the Carsten Niebuhr expedition, which passed nearby in 1763, and Ulrich J. Seetzen, in about 1810. The Austrian South Arabist Eduard Glaser visited the site in the late nineteenth century. Interest in the site increased again in the 1960s and 1970s, with research surveys by Giovanni Garbini, Wolfgang Radt, Walter W. Müller, Paolo Costa, and Raymond Tindel.

Today the site of Ẓafar is a ruin. No major Ḥimyarite features survive. Its condition is the result of war, earthquake, and the heavy reuse of its building stones. The site is situated on a somewhat elongated hilltop whose lower, broader, southern end is occupied by a small village and a museum. A rubble-strewn acropolis rises above the village. Foundations and retaining walls can be traced at some points, and various chambers and tunnels have been cut into the soft rock of the hillside. The valley to the west of Ẓafar is fertile and receives sufficient rainfall to support agriculture. Remains of Ḥimyarite dams, aqueducts, and terrace walls are found throughout the vicinity.

The most comprehensive description of the site is preserved in the *Al-Iklil* by the tenth-century Yemeni historian al-Hamdani. He listed three palaces: Raydan, Shawhatan, and Kawkaban, and named nine city gates. Raydan, the oldest known Ḥimyarite royal palace, probably occupied the acropolis; it is often attested in Ḥimyarite inscriptions and the acropolis at Ẓafar is still known locally by that name. Shawhatan, which is also mentioned in an inscription (*RES* 3383), probably occupied the northernmost extension of the acropolis, which was still known in the nineteenth century as the Fortress Shawhat. A dedicatory inscription (*ZM* [Ẓafar Museum] 1; published by Garbini, 1969) mentions a fourth palace, *HRGB* (vocalization uncertain). A church was built at Ẓafar as the result of the mission of Theophilus Indus, in about 350; three other churches may have been built there during an Ethiopian intervention in the sixth century. The names of other, nonroyal buildings are also known from various dedicatory inscriptions. In one instance the dedicant was clearly Jewish and included a brief Hebrew formulary in his otherwise South Arabic inscription. Nothing survives of the churches at Ẓafar except, perhaps, for a small cross in relief built into a house in a nearby village.

It is the anonymous building rubble covering the site that provides the best cultural profile of Ḥimyarite Ẓafar: fragmentary architectural elements, bas-reliefs, inscriptions, and sculpture. Stylistically, its motifs can be grouped into two broad categories. The first is the geometric style indigenous to South Arabia. Its elements include rectilinear stepped recess panels and polygonal columns with layered rectilinear capitals. It includes only a few naturalistic motifs such as ibex and bull heads. The motifs of the second are drawn from the orientalized Hellenism of Late Antiquity. Its elaborate vine scrolls, staring frontal busts, winged Victories, griffons, sphinxes, and fantastic hybrid creatures are well attested at Ẓafar. A considerable range of skill both in composition and execution is found in this second category. There is very little mingling of elements from the two categories.

These remains probably date primarily from the fourth and fifth centuries, during the period that Ẓafar was the undispute capital of Ḥimyar, and Ḥimyar the overlord of all of South Arabia. Unfortunately, historical sources for this period are very sparse. The less scrupulous execution of the few inscriptions that survive from this period suggest a general cultural decline. Sectarian rivalry between Christians and Jews exploded into violence during the early sixth cen-

tury, leading to intervention by both Ethiopia and Persia. Ẓafar, the scene of sieges and massacres, was abandoned as a capital. South Arabia ended the pre-Islamic period as a Persian dependency with a Sasanian governor ruling from San'a. Ẓafar gradually declined to the small village it is today.

ZAKKUR INSCRIPTION. The ZKR inscription occupies the front (A. 1–17), right (B. 1–28), and left sides (C. 1–2) of a fragmentary basalt stela discovered in 1903 by H. Pognon at Afis, 40 km (25 mi.) southwest of Aleppo, Syria, and published by him in 1908. It contains lacunae throughout, especially from A. 15 onward; however, the surviving text is legible, allowing a reasonably clear reconstruction of its contents.

The stela, honoring a little-known deity, 'LWR ('Iluwēr?), is dedicated by Zakkur, king of Hamath and L'Š (probably Lu'ath, ancient Nuḥašše). The body of the inscription commemorates the invasion of a coalition of perhaps sixteen rulers, led by Bar-Hadad, king of Damascus, that besieged the city of ḤZRK (assumed to be the capital of Lu'ath; cf. the Akkadian Ḥatarikka and Ḥadrāk in *Zec.* 9:1). Zakkur appealed to the Syro-Palestinian sky god Baal-Shamayn (Ba'al Shamêm), who promised deliverance through prophetic functionaries (A. 2–B. 3)—a deliverance apparently described in the missing and fragmentary lines following A. 17. Zakkur then describes his subsequent building program (B. 4–15), including a probable reference to Afis itself (B. 11, 'PŠ). A typical invocation of curses and blessings concludes the inscription (B. 16–C. 2; cf. the Sefire and Nerab inscriptions). [*See* Sefire Aramic Inscriptions; Nerab Inscriptions.] Such a combination of dedicatory offering with historical commemoration finds parallels in other Northwest Semitic inscriptions (e.g., from Karatepe and Mesha). [*See* Karatepe Phoenician Inscriptions; Moabite Stone.]

Bar-Hadad's identification as the son of Hazael (A. 4) associates this inscription with one phase of Israel's perennial wars against the Arameans (cf. *2 Kgs.* 8–14). [*See* Arameans.] Bar-Hadad III (or II) succeeded his father in about 800 BCE, after which point the fortunes of Damascus declined (see *2 Kgs.* 13:22–25, 14:23–28). This decline was undoubtedly hastened by the western campaigns of the Assyrian ruler Adad-Nirari III (810–783 BCE) in 805–803/802 and 796; undated inscriptions referring to the defeat of Damascus and payment of tribute by Joash of Israel would belong to one of these campaigns (most plausibly 796). [*See* Assyrians.] Damascus—and Ḥatarikka—were again the object of an Assyrian expedition in 773/72. The motives and precise historical background of Bar-Hadad's campaign are not clear. One interpretation views Zakkur as an Assyrian loyalist attacked by an anti-Assyrian coalition and rescued by Adad-Nirari in 796 (cf. *2 Kgs.* 16:5–18). Alternatively, Zakkur may have threatened the local balance of power by uniting Hamath and Lu'ath and so prompted retaliation. The inscription would have been composed in approximately 800–775 BCE.

Apart from its historical significance, the inscription sheds light on the religion of the area (A. 2–4, 11–17). Many details find parallels in the Hebrew Bible (e.g., *Is.* 36–38; *2 Chr.* 20:1–23): the lifting of hands in prayer to avert a crisis; the deity's answer through seers and messengers (?, *'ddn,* A. 12); and the assurance of deliverance based on divine election of the king. (cf. the Ugaritic prayers in *KTU* 1.40 and 1.119.26–36 and the role of prophetic intermediaries at Mari, Emar, Byblos, Deir 'Alla and—implicitly—in the Moabite Stone, ll. 14 and 32.) [*See* Ugaritic Inscriptions; Mari Texts; Emar Texts; Byblos; Deir 'Alla Inscriptions.] Of linguistic significance are the form and poetic content of the text, and three apparent *wayyiqtol* forms that are almost unique in Aramaic (A. 11, 15; cf. Deir 'Alla inscriptions).

DAVID M. CLEMENS

ZERAQUN, KHIRBET EZ-, site located about 13 km (8 mi.) northeast of Irbid, Jordan, about 2 km southeast of el-Mughayyir (both the village and the ancient mound). The site was first identified by Siegfried Mittmann in 1970. Joint excavations were carried out by Moawiyah Ibrahim for the Institute of Archaeology and Anthropology of Yarmouk University, Jordan, and Mittmann for the Biblisch Archäologisches Institute of the University of Tübingen. Fieldwork was conducted in cooperation with the Department of Antiquities of Jordan.

In five seasons of excavation (1984, 1985, 1987, 1988, 1991) and one survey season (1989) sites located in the triangle of Wadi esh-Shallalah and Wadi Rahub were investigated and Tell el-Mughayyir and Khirbet ez-Zeraqun were excavated. In the 1987 season, with surveyors from the University of Karlsruhe under the direction of Boser, a photogrammetric survey of the Roman bridge spanning Wadi esh-Shallalah, just southeast of Zeraqun, was completed. The bridge, built in two-story arches, is evidence of the Roman road link between Umm Qeis (Gadara) and Dar'a (Adraat). [*See* Umm Qeis.]

The site covers the remains of an Early Bronze occupation and has an area of about 400 × 300 m. It is one of the largest EB towns in Jordan or even southern Bilad ash-Sham ("greater Syria"). Khirbet ez-Zeraqun has a very similar occupational history to EB Bab edh-Dhra' in southern Jordan's Rift Valley. [*See* Bab edh Dhra'.] Excavations were concentrated in two major areas, in the upper and the lower town, adjacent to the town wall on its west and south sides.

The earliest occupational phase seems to date to the Late Chalcolithic/EB I period (beginning of the third millennium), represented by some domestic remains founded on bedrock that underlie the level of the walled town and the EB II–III public buildings and major domestic quarters. The second major phase dates to the EB II, when the site's major buildings were constructed: a 7-meter-wide defensive wall surrounding the town with projecting towers and bastions, a city gateway, a temple complex, and an administration building, all in the upper town. Other buildings belonging to this period were large to small rooms in the lower town, some of which were for domestic use. The third major phase of occupation (EB III) was represented by significant changes and additions to the main architectural complexes (the gateway, town wall, and houses in the lower town). From the EB IV toward the end of the third millennium the fourth and latest occupation is represented by fragmentary disturbed structures close to the surface and a few silos lined with stones dug into earlier deposits.

There are scattered sherds from the Roman-Byzantine period on the surface and in disturbed areas, but they are not associated with structures. Other remains of a later use of the site are a large number of nineteenth-century burials dug into the EB layers. There are also several modern ditches and disturbances. The site was used until recently for agriculture. It is barren of trees and modern houses.

Town Gate. During the last two seasons of excavations, the town's main gate was excavated close to the highest point on the west side of the site. The gate showed four major changes during different EB periods. The earliest stage represents the widest opening (about 15 m). During the following phases it became progressively narrower, until it was reduced to a small, zigzag passageway. Its exterior features two curving, towerlike additions, while the inner part of the wall is connected to two square towers. The inner towers, with other, adjacent rooms, surround a road that leads directly to the temple area and the industrial quarter. The floor of the gate and the passageway consists of beaten earth and areas paved with small stones. The gate is easily accessible from the gradual slope to the west of the site.

Temple Complex. The main cultic area dominates the town and surrounding areas. It is accessible from the site's northwest side via the road coming from the gate's passageway, and from the east via a long street (about 1.5 m wide) on the south side of the administration building (see below). On the west side there seems to be a small gap between the town wall and the temple. The complex consists mainly of a circular altar with a staircase on the east side and large square and rectangular rooms, all surrounding a large open courtyard. With the exception of the large rectangular cult room, all the buildings are oriented east–west, toward the circular altar. A row of storage rooms, designated as the industrial quarter, on the northeast side of the complex have been uncovered.

Administration Building. An administrative architectural complex was exposed on the north side of the east–west street. It is separated from the temple area by a narrow, irregular corridor. This unit consists of rectangular rooms surrounding a large outstanding room, all built of stone with bricks probably used in their upper parts. The arrangement of the rooms in this unit and their connections to the temple and to the rooms in the industrial area indicate that the unit served administrative purposes. Confirmation of this interpretation awaits further excavations and analysis of the material found in the complex.

Lower Town. Excavations in five seasons exposed sections of the city wall and a residential area on the south side of the site. The architectural remains in this area represent

two and possibly three major occupational phases (EB I/II–III). The earlier phase, founded on bedrock, revealed planned architecture oriented east-west around a main street, with subsidiary streets creating separate residential units. The phase could be subdivided into two parts because of changes in the architecture and additional floors. The second major architectural phase is less organized in plan and reveals a new street arrangement. A semicircular tower was found outside the city wall. To the east of the tower, and along the exterior face of the city wall, several horizontal stone slabs were uncovered. They are believed to have been used as steps leading to a higher part of the fortification system. Excavations also revealed a tower on the interior that probably supported the town wall. At the lowest part of the tower, a water channel was discovered. This channel was built to draw off the water running down from the upper town toward the fortification and may have limited the damage caused by runoff.

Water System. The town's highly developed hydrological system must have governed life there for almost a thousand years. In addition to the springs of Wadi esh-Shallalah, the inhabitants of Zeraqun dug three stepped shafts down to the water table. One of these shafts measures some 100 m and leads to the base of the wadi. It is probable that the water of this shaft system was used during enemy attack and when spring water in the surrounding area dried out. At the steep slope toward the wadi closable water outlets were found connected to the shafts that were probably used to water the fields in the wadi. [*See* Hydraulics; Irrigation; Water Tunnels.]

Small Finds. Among the important objects excavated at Zeragun was a large number (about 120) of seal impressions on pottery, which makes the town the richest site for glyptic in third-millennium. Transjordan and Palestine. [*See* Seals.] The impressions show geometric, floral, animal, and figural designs. The seal impressions, the large variety of pottery types, and clay figurines reveal close parallels and contacts with Palestine, Egypt, Anatolia, Mesopotamia, and North Syria. Together with other discoveries, they also show Khirbet ez-Zeraqun to have been a flourishing EB city.

MOAWIYAH IBRAHIM and SIEGFRIED MITTMANN

ZEROR, TEL (Ar., Khirbet et-Tell Dhurur), site located on the northern Sharon plain, near an ancient crossing of the Ḥadera River, on the western branch of the Via Maris (32°28′ N, 35°01′ E; map reference 1476 × 2038). The 6-ha (15 acres) mound is composed of two spurs connected by a lower saddle. The mound's cemetery (Late Bronze II–Iron I periods) extends over a low hill 150 m west of the mound. The site was excavated by Kiyoshi Ohata on behalf of the Japanese Society for Near Eastern Research in 1964–1966 and in 1974; Moshe Kochavi was field director during the 1964–1966 seasons, and Koichito Goto was field director in 1974. Benjamin Mazar and Nadav Na'aman suggested the site's identification with DRR, number 115 in Thutmose III's topographical lists; Yohanan Aharoni proposed MKTR on the same list (MGDL YN in the Annals of Amenhotep II).

The first occupation of Tel Zeror took place at the beginning of the Middle Bronze Age and the last was in the Early Roman period, but remains of not all these periods were found uniformly across the mound. Four strata were assigned to MB I, the only MB phase during which the city existed. Two superimposed city walls were excavated in various areas, which made it possible to follow most of their course. The walls had stone foundations laid on an earthen rampart. A wide moat and a two-chambered tower were found on the western side of the mound. The early city was deserted before the transitional MB I–II phase, and there was an occupation gap in MB II–III.

The Late Bronze settlement had no fortifications, but a major public building was constructed on the mound's southern spur, on whose slope coppersmiths' quarter existed throughout the period. Smelting furnaces, crucibles, clay bellows pipes, and copper slags were found there in abundance. The high percentage of Cypriot pottery found in the coppersmiths' quarter may point to Cyprus as the source of the raw material used there. Burials from the fourteenth to thirteenth centuries BCE were uncovered in the cemetery. These were individual graves cut in the soil, sometimes lined with small stones. The bodies were placed with their heads facing west. [*See* Burial Techniques.]

Two different types of settlement were observed for the Iron Age I. The earliest dated to the twelfth century BCE, and from it only refuse pits containing pottery sherds and animal bones were found. Several burials in collar-rim jars, exposed in the cemetery, were also attributed to this phase. In the later phase (eleventh century BCE) a brick fort with a casemate wall was built on the northern spur. The tombs in the cemetery were family graves in stone-lined cists. They contained many weapons, some copper bowls, and a unique pinched type of oil lamp. A rhyton in the shape of a lioness and a plaque figurine of a naked female were also among the rich finds from these tombs. [*See* Tombs; Grave Goods; Lamps.] During Iron II the settlement continued to be concentrated on the southern spur. Storehouses and pillared four-room houses were exposed, protected by a thin wall

strengthened on its interior with half-meter-wide piers set at 2-m intervals. [*See* Four-room House.] The village well was also unearthed, on the low ground south of the northern spur. Among the finds from this period are an Aramaic inscription on a bowl that reads L'LSMK ("belonging to Elsamakh"); a "Resheph" bronze figurine; a steatite bowl with a hand carved on its base; and storage jars with the letter *mem* inscribed on their bodies. Pits dug in the Persian period were found on the northern spur, where a farmhouse was erected in the third–second centuries BCE. The last occupation on the northern spur was an Early Roman watchtower. The remains of the village of Khirbet et-Tell Dhurur, on the southern spur, dated to the Mamluk period.

MOSHE KOCHAVI

ZIGGURAT. Like modern skyscrapers or medieval cathedrals, Mesopotamian ziggurats served as the visual foci of Mesopotamian cities, providing a symbol of the power of the city and its god visible for miles around. A true ziggurat is a stepped pyramid, square or rectangular in plan, with a temple on top, but this form was not arrived at immediately: the earliest Mesopotamian shrines were built flush with the ground. The sacredness of the shrine structure led to new temples being built on platforms, within which earlier versions were entombed. This development is seen especially clearly at Eridu, where a very small early Ubaid shrine developed over time, first into a standard Mesopotamian temple built on a platform and eventually into a true ziggurat. [*See* Eridu.] Moreover, from a very early period, as with the so-called Anu Ziggurat that supported the fourth-millennium White Temple at Uruk, attempts were made to raise major religious buildings above the rest of the city. [*See* Uruk-Warka.]

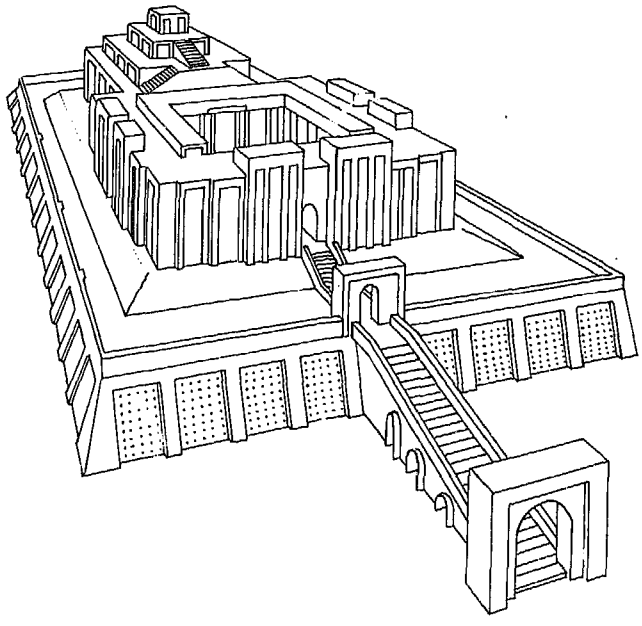
Temple platforms of varying degrees of complexity were built throughout the third millennium, but true ziggurats are not clearly attested until the Third Dynasty of Ur. [*See* Ur.] Both archaeological data and textual sources indicate that from the late third millennium onward, virtually all major cities had ziggurats. The existence of some ziggurats, notably those at Susa and Nineveh, however, is known from textual evidence only. [*See* Susa; Nineveh.] Although the distribution of well-understood ziggurats over time and space is very uneven, they appear to have come in two varieties: the generally earlier and Babylonian one had a rectangular base with stairs providing access to the top; the later one, more often found in Assyria, is square in plan and had more variable access, sometimes including a ramp that spirals up the building.

The archaeological evidence is much better for the Babylonian ziggurats than for the Assyrian variety. Excavations have been carried out on the former at Eridu, Ur, Uruk, Nippur, Sippar, and ʿAqar Quf; the ziggurats at Kish, Borsippa, and perhaps even Babylon and Larsa probably also fall into this category. [*See* Nippur; Sippar; ʿAqar Quf; Kish; Babylon; Larsa.] All these buildings have their corners oriented to the cardinal points and were generally located, together with a lower temple, within a courtyard with a separate forecourt. The shrine at the top was reached by means of staircases often with a triple stair—one perpendicular to the wall face and the other two running along the wall from the two corners—leading up to the first stage of the ziggurat and meeting at a gateway. Only at Ur is the second stage sufficiently preserved for it to be clear that only a single stair provided access to its top.

These ziggurats all had a core of mud bricks, within which earlier buildings were often encompassed. The exterior was generally of baked brick, often several meters thick and sometimes mortared with bitumen. These outer walls were decorated with buttresses, some of which were quite complex. Most of these ziggurats included some form of drainage—either in the form of reed mats interlayered with the mud brick, of reed ropes running from one side of the structure to the other, or of holes, sometimes filled with broken potsherds, also running from one side of the ziggurat to the other.

The later and northern ziggurats are typified by those at Khorsabad, Aššur, Nimrud, Kar-Tukulti-Ninurta, and Tell er-Rimah (see figure 1); some scholars argue that the ziggurat at Larsa resembled them. [*See* Khorsabad; Aššur; Nimrud; Kar-Tukulti-Ninurta; Rimah; Tell er-.] The Khorsabad example preserves clear evidence of a ramp, which spiraled up its height, and of some of the different colors with which the different stages were painted: from bottom to top, black, white, orange, blue, red, silver, and gold—each color representing one of the planets or, in the case of silver and gold, the moon and the sun. Seven stages, reflecting these astronomical associations, seems to have been quite typical of later ziggurats, whether found in Assyria or Babylonia.

The siting of the Assyrian ziggurats was also different. All were built into temple complexes, and at Aššur, Kar-Tu-



ZIGGURAT. Figure 1. *Reconstructed drawing, temple and ziggurat at Tell er-Rimah.* Perhaps built c. 1800 BCE, around the time of Shamshi-Adad I. The ziggurat was part of the temple building and the upper shrine was probably reached from the roof of the courtyard temple. (Courtesy Andromeda Oxford, Ltd.)

kulti-Ninurta, and Tell er-Rimah, they represented no more than the highest of three platforms: the first acted as a forecourt, the second bore the temple, and the third consisted of the ziggurat or, in the case of Aššur, ziggurats. In general, these Assyrian ziggurats were more variable in their orientation, in the type of access—by stair, ramp, or even bridge—and in the degree to which they were incorporated into larger building complexes than their Babylonian forebears; however, they were quite consistent in their square form and perhaps in the number of stages.

In spite of the variability both within and between types, the function of Mesopotamian ziggurats—to support the temple of the city god—remained constant. Ziggurats represent an enduring monument to the important role of religion in defining the political importance of Mesopotamian cities. It was the ziggurat at Babylon, for example, dedicated to Marduk and known as Entemenanki ("the temple of the foundation of heaven and earth") that inspired the later biblical legend of the Tower of Babel (*Gn.* 1:4–9).

ELIZABETH C. STONE

ZIQLAB, WADI, stream that drains an area in modern Jordan of 115 sq km (21 sq. mi.) north of the Wadi Yabis drainage basin and immediately south of Wadi Taiyiba. Its eastern watershed is on the Irbid plateau and its mouth is in the Jordan Valley. The drainage occupies the greater part of the al-Kura administrative district, whose center is at Dayr Abu Sa'id.

Although several nineteenth-century travelers mentioned antiquities in this district, the first systematic archaeological surveys to include it were by Gottlieb Schumacher (1890; D. C. Steuernagel 1925, 1926), and Nelson Glueck (1951). One by Siegfried Mittmann (1970) followed, and the westernmost part of Wadi Ziqlab fell within the East Jordan Valley Survey (Ibrahim et al., 1976). The 1981 Wadi Ziqlab Project (Banning and Fawcett, 1983; Banning, 1985) was the first archaeological survey to focus specifically on the Ziqlab basin, sampling about 20 percent of its surface area as the target of a medium-intensity survey by transects 1 kilometer long. Test excavations at several, mainly small, Early Bronze–Ottoman-period sites followed in 1986 and 1987 (Banning et al., 1987; Banning et al., 1989). Excavations at Ṭabaqat al-Buma, with occupations in the Kebaran and Late Neolithic periods, took place in 1987, 1990, and 1992 (Banning et al., 1992).

The prehistoric periods in Wadi Ziqlab are represented by large numbers of deflated lithic scatters, mainly from the Middle and Upper Paleolithic periods, by Kebaran deposits at Ṭabaqat al-Buma (WZ 200, YA547996*); and by at least four Neolithic sites. 'Ain Ṣabḥa (WZ 120, YB496012) has 4 m of cultural deposits from the Pre-Pottery Neolithic B (PPNB) and the Late Neolithic and EB Ages. The Wadi Summayl site (WZ 119, YA559969) is probably Late Neolithic. Ṭabaqat al-Buma (WZ 200) has more than a meter of deposits, with stone architecture belonging to three distinct Late Neolithic strata. Site WZ 310 (YB542000) shows occupation from the Late Neolithic through EB I. A small sample of lithics in secondary deposition at locality WZ 308 (YB536002) suggests that there may be another Neolithic site in the vicinity.

The principal EB sites in the catchment are Khirbet Maḥrama (WZ 60, YA620905), sounded in 1986, and Tell al-Arba'in (YB433011), near the wadi's mouth. At Maḥrama, at least 1.5 m of deposit belong to EB I–II. The site is capped by relatively shallow Roman–Byzantine deposits and Mamluk and Early Ottoman ruins. Glueck (1951) and Ibrahim et al. (1976) report EB I material at Arba'in; Glueck also notes some EB I–II material at Tell Abu al-Fokhkhar (WZ 43, YB487014) and Khirbet Sibya (YB530021).

No survey of Wadi Ziqlab to date has found more than slight evidence for occupation from EB III through to the end of the Late Bronze Age (notably MB II at Tell al-Arba'in), and that mainly at lower elevations. However, there is abundant evidence for Iron I and II occupation throughout the basin. Some of this consists of towers (e.g., WZ 9, YA555975 [Banning et al., 1989]), Ras Birqish, WZ 10, YA566927), but mainly there are scatters of pottery and ruined architectural traces of Iron Age villages, such as Sibya and Jebatun (WZ 70, YA579980). Iron Age expansion probably involved clearing forests and terracing hillsides.

Khanzira (Ashrafiya, YA544957), near Ziqlab's southeast watershed, appears to have been the main center for a sparse Hellenistic occupation of the region, followed by extremely intensive use of the basin during the Roman, Byzantine, and Umayyad periods. In the later periods, villages, hamlets, and probably farmsteads or villas dot the landscape, and numerous terraces, wine presses, cisterns, and olive presses attest to thriving agriculture, viticulture, and arboriculture. Tell Abu al-Fokhkhar (WZ 43, YB487014) and Marḥaba (WZ 106, YB514004) appear to have been important sites then, the former with a temple or church on its citadel, the latter with a church and a mosaic.

The next major occupation of the basin was during the Mamluk period, when many of the modern villages were already occupied, and occupation was resumed at Khirbet Maḥrama. During the last century of Ottoman rule, many of these villages were abandoned, and Tubna (YA 546967) became the preeminent village of al-Kura, with its eighteenth-century Zaydani castle and mosque and nineteenth-century ruling Shrayda family.

TABLE 4. *Two Stone Plaques*

Museum/Library Number; Acquisition Source	Item Description	Place and Date of Discovery	Initial Publications	Fitzmyer/ Kaufman
1. Ashmolean Museum, Oxford, Aramaic Ostracon 1	Limestone plaque dated 19 Aug. 403 BCE	Memphis; pre-1909	Cowley, in Petrie, *Apries*, pp. 12-13; Lemaire, *Semitica* 37 (1987): 52-55	B.3.e.11
2. Berlin P. 11385; Rubensohn	Opisthographic granite fragment with six names	Elephantine; 1906–1907	Sachau 79 (Pl. 66,2)	B.3.c.50

TABLE 5. *Six Wooden Pieces (not including Mummy Labels)*

1. Ägyptisches Museum, Berlin 11361; Friedrich Zucker	Opisthographic fragment with hole at top	Elephantine; 1907–1908	Sachau 83 (Pl. 70,15)	
2. ÄM, Berlin 18468 (Sachau: incorrectly 18462); Otto Rubensohn	Mummy label with string; name and title	Elephantine; 1906–1907	Sachau 84 (Pl. 71,12)	B.3.c.53
3. ÄM, Berlin 19435; Zucker	Palette fragment?; personal name	Elephantine; 1907–1908	Sachau 81 (Pl. 68,3) = Aimé-Giron, *BIFAO* 34 (1934): 86-87	B.3.c.54
4. Brooklyn Museum 16.99; Charles E. Wilbour	Palette; obscure inscription	Elephantine; 1893	Aimé-Giron 119 = *BIFAO* 38 (1939): 47-57	
5. Louvre AF 11016	Opisthographic palette; accounts	Provenance unknown	Lemaire, *Semitica* 37 (1987): 47-55	B.3.f.35
6. Medinet Maadi (Narmuti)	Handled stamp; name + verb	Medinet Maadi (Narmuti); 1966	Bresciani, *Medinet Maadi*, 30-32	

TABLE 6. *Six Seals and Bullae (not including Wooden Pieces)*

1. Aimé-Giron; personally acquired	Eight-sided cone	Provenance unknown	Aimé-Giron 116 = *BIFAO* 38 (1939): 43-45	
2. Aimé-Giron; personally acquired	Light, striped, ellipsoidal agate cylinder	Provenance unknown; 1934	Aimé-Giron 117 = *BIFAO* 38 (1939): 45-47	B.7.1.34
3. Bodleian Library, Oxford Sigill. aram. VIII., lap. insc. impr.	Bulla	Provenance unknown	Driver, *Aramaic Documents*, 4, n. 1	B.7.1.66
4. Egyptian Museum, Cairo JE 25225	Quartz scaraboid seal	Saqqara?; 1882	CIS, vol. 2.1, 124 = Herr 1	B.7.1.157
5. Israel Museum, Jerusalem 71.46.91	Black agate scaraboid seal	Provenance unknown; pre-1954	Reifenberg, *IEJ* 4 (1954): 139	
6. Pushkin Museum, Moscow, Seal N I, 2B 255; Vladimir Golénischeff	Chalcedony scaraboid seal	Provenance unknown; pre-1868	CIS, vol. 2.1, 140 = Herr 6	B.7.1.64

TABLE 7. *Three Statuettes*

Museum/Library Number; Acquisition Source	Item Description	Place and Date of Discovery	Initial Publications	Fitzmyer/ Kaufman
1. Egyptian Museum, Cairo JE 31919	Red granite headless statue with name	Provenance unknown; 1897	*RÉS* 965 = *ESE*, vol. 3, 117-18	
2. Cairo JE 35562; Archibald Henry Sayce	Sandstone statue with fragmentary name	Qubbet el-Hawa; 1889	Maspero, *ASAE* 3 (1902): 96; Daressy, *ASAE* 17 (1917): 81-85; Ronzevalle, *ASAE* 17 (1917): 270-271	
3. Pisa; personally acquired	Clay statuette with lament	Provenance unknown	Bresciani, *Hommages Dupont-Sommer*, pp. 5-8	B.3.f.31 "possibly a forgery"

TABLE 8. *Five Libation Bowls*

1. Brooklyn Museum 54.50.32; Charles Edwin Wilbour Fund	Silver bowl with dedication	Tell el-Maskhuta pre-1956	Rabinowitz, *JNES* 15 (1956): 4-5 = Grelot 79	B.3.f.12
2. Brooklyn Museum 54.50.34; Wilbour Fund	Silver bowl with dedication	Tell el-Maskhuta pre-1956	Rabinowitz, *JNES* 15 (1956): 5-9 = Grelot 78 = Gibson 25	B.3.f.12
3. Brooklyn Museum 54.50.36; Wilbour Fund	Silver bowl with dedication	Tell el-Maskhuta pre-1956	Rabinowitz, *JNES* 15 (1956): 2–4	B.3.f.12
4. Brooklyn Museum 57.121; Wilbour Fund	Silver bowl with dedication	Tell el-Maskhuta pre-1956	Rabinowitz, *JNES* 18 (1959): 154-156; Honeyman, *JNES* 19 (1960): 40-41	B.3.f.12
5. Stockholm, Sweden; currently in Carl Kempe collection; Robert Erskine	Silver bowl with name	Provenance unknown; c. 1956	Bivar, *BSOAS* 24 (1961): 189–199; Hinz, 237	B.3.f.38

TABLE 9. *Nine Mummy Labels*

1. Ägyptisches Museum, Berlin 18464; Otto Rubensohn	Wooden	Elephantine; 1906–1907	Sachau 84 (Pl. 71,13)	B.3.c.52
2. Egyptian Museum, Cairo JE 54157; Gustave Jéquier	Ceramic; inscribed on convex	South Saqqara; 1929–1930	Aimé-Giron 109	B.3.e.27
3. Cairo JE 54158; Jéquier	Ceramic	South Saqqara; 1929–1930	Aimé-Giron 111b (see Aimé-Giron 111a)	B.3.e.27
4. Cairo JE 54159; Jéquier	Ceramic; inscribed on convex	South Saqqara; 1929–1930	Aimé-Giron 105	B.3.e.27
5. Cairo JE 54160; Jéquier	Ceramic	South Saqqara; 1929–1930	Aimé-Giron 112b (see Aimé-Giron 112a)	B.3.e.27
6. Cairo JE 54161; Jéquier	Ceramic	South Saqqara; 1929–1930	Aimé-Giron 110b (see Aimé-Giron 110a)	B.3.e.27
7. Cairo JE 55033; Jéquier	Limestone	South Saqqara; 1929–1930	Aimé-Giron 102 (see Aimé-Giron 96, 108)	B.3.e.27
8. Lost; Jéquier	Stone	South Saqqara; 1930	Aimé-Giron 118 = *BIFAO* 38 (1939): 46	B.3.3.20
9. Cairo JE 63379	Wooden	South Saqqara	unpublished	

TABLE 10. *Twenty-two Inscribed Sarcophagi*

Museum/Library Number; Acquisition Source	Item Description	Place and Date of Discovery	Initial Publications	Fitzmyer/ Kaufman
1. Aswan Museum 2605; El-Hetta	Painted sandstone anthropoid sarcophagus; at base, engraved inscription	Aswan; 1963	Kornfeld, *WZKM* 61 (1967): 9-10, 12-13	B.3.f.4
2. Aswan Museum 2606; El-Hetta	Painted sandstone anthropoid sarcophagus; at base, engraved inscription	Aswan; 1963	Kornfeld, *WZKM* 61 (1967): 10-11, 13	B.3.f.4
3. Aswan Museum 2607; El-Hetta	Painted sandstone female anthropoid sarcophagus; at base, engraved inscription	Aswan; 1963	Kornfeld, *WZKM* 61 (1967): 11-14	B.3.f.4
4. Egyptian Museum, Cairo JE 55213; Gustave Jéquier	Ceramic coffin lid	South Saqqara; 1929–1930	Aimé-Giron 101	B.3.e.27
5. Cairo JE 55214a, b; Jéquier	Ceramic coffin lid; left exterior	South Saqqara; 1928–1929	Aimé-Giron 104a, c	B.3.e.27
6. Cairo JE 55215a, b; Jéquier	Ceramic coffin lid; left exterior	South Saqqara; 1929–1930	Aimé-Giron 103a, c	B.3.e.27
7. Cairo JE 55217; Jéquier (same vessel as JE 55224)	Ceramic coffin lid	South Saqqara; 1929–1930	Aimé-Giron 97a	B.3.e.27
8. Cairo JE 55218; Jéquier	Ceramic coffin left exterior	South Saqqara; 1928–1929	Aimé-Giron 99 = Grelot 76	B.3.e.27
9. Cairo JE 55219; Jéquier	Ceramic coffin left exterior	South Saqqara; 1929–1930	Aimé-Giron 111a (see Aimé-Giron 111b)	B.3.e.27
10. Cairo JE 55220; Jéquier	Ceramic coffin left exterior	South Saqqara; 1929–1930	Aimé-Giron 110a (see Aimé-Giron 110b)	B.3.e.27
11. Cairo JE 55221; Jéquier (same vessel as JE 55222)	Ceramic coffin right exterior	South Saqqara; 1929–1930	Aimé-Giron 100b	B.3.e.27
12. Cairo JE 55222; Jéquier (same vessel as JE 55221)	Ceramic coffin lid	South Saqqara; 1929–1930	Aimé-Giron 100a	B.3.e.27
13. Cairo JE 55223; Jéquier	Ceramic coffin right interior	South Saqqara; 1929-1930	Aimé-Giron 112a (see Aimé-Giron 112b)	B.3.e.27
14. Cairo JE 55224; Jéquier (same vessel as JE 55217)	Ceramic coffin left exterior	South Saqqara; 1929–1930	Aimé-Giron 97b	B.3.e.27
15. Cairo JE 55225; Jéquier	Ceramic coffin exterior	South Saqqara; 1929–1930	Aimé-Giron 106	B.3.e.27
16. Cairo JE 55226; Jéquier (same vessel as JE 55227)	Foot of ceramic coffin	South Saqqara; 1929–1930	Aimé-Giron 96c	B.3.e.27
17. Cairo JE 55227; Jéquier (same vessel as JE 55226)	Ceramic coffin lid	South Saqqara; 1929–1930	Aimé-Giron 96a, b (see Aimé-Giron 102)	B.3.e.27
18. Cairo JE 55228; Jéquier	Ceramic coffin left exterior	South Saqqara; 1929–1930	Aimé-Giron 98	B.3.e.27
19. Cairo JE 55245; Jéquier	Ceramic coffin lid	South Saqqara; 1928–1929	Aimé-Giron 95	B.3.e.27

TABLE 10. *Twenty-two Inscribed Sarcophagi (Continued)*

Museum/Library Number; Acquisition Source	Item Description	Place and Date of Discovery	Initial Publications	Fitzmyer/ Kaufman
20. Cairo JE 55247; Jéquier	Foot of ceramic coffin	South Saqqara; 1928–1929	Aimé-Giron 108 (see Aimé-Giron 102)	B.3.e.27
21. Cairo JE 63380; Jéquier	Wooden fragment	South Saqqara; 1929–1930	Aimé-Giron 115 = *BIFAO* 38 (1939): 43	B.3.3.21
22. Disintegrated; Jéquier	Wooden lid	South Saqqara; 1929–1930	Aimé-Giron 107	

TABLE 11. *Fourteen Tombstones and One Memorial Stela*

1. Ägyptisches Museum, Berlin 18502	Limestone plaque with name	Abu Sir; 1907	Sachau 87 (pl. 74,4)	B.3.c.51
2. Greco-Roman Museum, Alexandria 5904; Evaristo Breccia	Limestone; painted inscription	El-Ibrahimiya (Alexandria); 1906	*RÉS* 798	B.3.f.39.3
3. Alexandria 18361; Breccia	Limestone; painted inscription	El-Ibrahimiya (Alexandria); 1906	*RÉS* 797	B.3.f.39.1
4. Alexandria, number not certain; Breccia	Tombstone; painted inscription	El-Ibrahimiya (Alexandria); 1906	*RÉS* 799	
5. Edfu Storeroom	Tombstone; incised inscription	Edfu	Kornfeld, *AÖAW* 110 (1973): 123-129; Kornfeld, *Kairos* 18 (1976): 58	B.3.f.41
6. Edfu Storeroom	Reused offering table; incised inscription	Edfu	Kornfeld, *AÖAW* 110 (1973): 129-130	B.3.f.41
7. Edfu Storeroom	Tombstone; incised inscription	Edfu	Kornfeld, *AÖAW* 110 (1973): 131; *NESE*, vol. 3, pp. 64-65	B.3.f.41
8. Edfu Storeroom	Tombstone; incised inscription	Edfu	Kornfeld, *AÖAW* 110 (1973): 131-132	B.3.f.41
9. Edfu Storeroom	Tombstone; incised inscription	Edfu	Kornfeld, *AÖAW* 110 (1973): 132-133	B.3.f.41
10. Edfu Storeroom	Tombstone; incised inscription	Edfu	Kornfeld, *AÖAW* 110 (1973): 133; Lipiński, *OLP* 6-7 (1975–1976): 382ff; *NESE*, vol. 3, pp. 63-64	B.3.f.41
11. Edfu Storeroom	Tombstone; incised inscription	Edfu	Kornfeld, *AÖAW* 110 (1973): 134	B.3.f.41
12. Edfu Storeroom	Tombstone; incised inscription	Edfu	Kornfeld, *AÖAW* 110 (1973): 134-135	B.3.f.41
13. Edfu Storeroom	Tombstone; incised inscription	Edfu	Kornfeld, *AÖAW* 110 (1973): 135; *AÖAW* 111 (1974): 376-378	B.3.f.41
14. Luxor Museum Storeroom (uncollated); Taher	Sandstone; incised inscription	Hagir Esna; 1971	Kornfeld, *AÖAW* 111 (1974): 374-376	
15. Paris; personally acquired	Memorial stela?	Provenance unknown	Aimé-Giron 110bis = Dupont-Sommer, *Syria* 33 (1956): 79-87 = Grelot 77	B.3.e.2

TABLE 12. *Five Funerary Stelae, One Offering Table, One Dedication*

Museum/Library Number; Acquisition Source	Item Description	Place and Date of Discovery	Initial Publications	Fitzmyer/ Kaufman
1. Berlin (Gipsformerei 939); Travers; destroyed in World War II	Stela; 1 register + hieroglyphic inscription + 2 registers + 4-line Aramaic inscription	Saqqara; pre-1877	CIS, vol. 2.1, 122 = *KAI* 267 = Grelot 85 = Gibson 23	B.3.3.22
2. Brussels (Musées Royaux d'Art et d'Histoire E.4716); Jean Capart and Franz Cumont	Stela	Provenance unknown; 1907	*RÉS* 1788; Lipiński, *CdÉ* 50 (1975): 93-104	B.3.e.29
3. Carpentras; Rigord	Stela; 2 registers + 4-line inscription	Provenance unknown; 1704	CIS, vol. 2.1, 141 = *KAI* 269 = Grelot 86 = Gibson 24	B.3.f.18
4. Saqqara; Cecil M. Firth	Fragmentary stela; 1-line inscription	Saqqara; 1926?	Aimé-Giron 114 = *BIFAO* 38 (1939): 40-43	
5. Vatican XI.32.21; Charles Lenormant	Stela; register + 1-line inscription + register	Provenance unknown; 1860	CIS, vol. 2.1, 142 = *KAI* 272	B.3.f.28
6. Louvre AO 4824; F. Auguste Mariette	Offering table; 4-line inscription	Serapeum, Memphis; 1851	CIS, vol. 2.1, 123 - Grelot 84 = *KAI* 268	B.3.e.8
7. Cairo JE 36448	Sandstone stela 6-line inscription	Aswan; pre-1903	*RÉS* 438, 1806 = Grelot 75	B.3.f.3

TABLE 13. *Fifty-one Graffiti (arranged from north to south)*

1. Giza; Imile Baraize; Egyptian Museum, Cairo, Temporary Register 29-12-28-1	1-line inscription	Sphinx column drum, 1928	Aimé-Giron 90	B.3.f.19
2. Ma'sarah; Archibald Henry Sayce	Personal name, above demotic cartouche of Achoris	Quarry south of Tura, 1886	*RÉS* 1819	B.3.f.37
3–5. Dahshur; Jacques J. M. de Morgan	3 graffiti: 1 fragment, 2 prenomina	Senwosret III pyramid	*RÉS* 1818; Aimé-Giron, p. 97, n. 1	B.3.f.36
6. Wadi Sheikh Sheikhun; Gaston Maspero and Eugène Grébaut	2-line proskynema	Large boulder near wadi entrance; 1886	CIS, vol. 2.1, 134 = RÉS 1817; *RAO* 6 (1905): 267-270	B.3.f.29
7-16. Abydos	10 proskynemata to Osiris	Seti I temple; 1868–1915	*ESE*, vol. 3, 103, No. Ag = RÉS 1368; *ESE*, vol. 3, 107, No. Al = RÉS 1364; *ESE*, vol. 3, 108, No. Ap = RÉS 608; *ESE*, vol. 3, 108, No. Aq = RÉS 1369; *ESE*, vol. 3, 109, No. As = RÉS 1370; *ESE*, vol. 3, 112, No. Bb = RÉS 1366 = Grelot 80; *ESE*, vol. 3, 113, No. Bf = RÉS 1373; Kornfeld, *AÖAW* 115 (1978): 199; *ESE*, vol. 3, 113, No. Bi = RÉS 1375; *ESE*, vol. 3, 114, No. Bk = RÉS 1376; *ESE*, vol. 3, 114, No. Bl = RÉS 1377	B.3.f.23

TABLE 13. *Fifty-one Graffiti (Continued)*

Museum/Library Number; Acquisition Source	Item Description	Place and Date of Discovery	Initial Publications	Fitzmyer/ Kaufman
17-18. Abydos	Two 4-line proskynemata (Anatolians?) (perhaps three distinct inscriptions)	Seti I temple; 1868–1915	*ESE*, vol. 3, 103, No. Aha = RÉS 1367 = Grelot 81; *ESE*, vol. 3, 103, No. Ahb = RÉS 1372 = Grelot 82; Aimé-Giron, p. 79; Dupont-Sommer, *Annuaire* (1966–1967), 119	B.3.f.23
19-24. Abydos; Ada Yardeni	4 personal names; 2 prenomina	Seti I temple; 1868–1915, 1993	*ESE*, vol. 3, 98, No. J = RÉS 1371; *ESE*, vol. 3, 107, No. Am = RÉS 1363; Kornfeld, *AÖAW* 115 (1978): 198; *ESE*, vol. 3, 109, No. Ar = RÉS 1370; *ESE*, vol. 3, 113, No. Bh = RÉS 1374; (unlocated; perhaps illusory) CIS, vol. 2.1, 133, contra Kornfeld, *AÖAW* 115 (1978): 202; 1 unpublished	B.3.f.23
25. Wadi Hammamat; J.-C. Goyon	Abecedary	Black granite; 1946	Dupont-Sommer, *RA* 41 (1947): 105-110	B.3.f.10
26-32. Wadi Abu Qwei; Arthur Weigall, Luisa Bongrani-Fanfoni	5 proskynemata; 2 personal names	Wadi inside Wadi Hammamat; 1907, 1989	Weigall, *Travels in the Upper Egyptian Deserts*, Pl. 7.15; Fanfoni-Israel, *Transeuphratène* 8 (1994): 81-93	
33-36. Gebel Abu-Gurob; Sayce	4 personal names	Between Heshan (=Hosh?) and Wadi el-Shatt er-Rigal; 1907	Sayce, *PSBA* 30 (1908): 28-29 (readings uncertain)	
37-41. Wadi el-Shatt er-Rigal; Petrie (2); Sayce (4)	4 proskynemata	Near large rock at northern entrance of wadi; 1887, c. 1890	CIS, vol. 2.1, 135, 136 = RÉS 960, 961, 962, 962 = Sayce, *RT* 17 (1895): 164, Nos. 5-6	
42. Aswan; Sayce	3 incisions of same word	Sandstone quarry	Sayce, *PSBA* 28 (1906): 174-75	
43-48. Wadi el-Hudi, Ibrahim Effendi 'Abd el-'Al (Cairo JE 71901)	5 proskynemata; 1 personal name	Stela on hill at amethyst quarries; 1939	Aimé-Giron 124 = *ASAE* 39 (1939): 351-363	B.3.f.20
49-50. Tomas; Weigall	2 personal names	Sandstone; 1906–1907	Weigall, *Report on the Antiquities of Lower Nubia*, 113 + Pl. 64.6; Aimé-Giron 92-93	B.3.f.1.2-3
51. Unknown; Henry Salt; bought by W.T. Ready, 20 June 1899	Prenomen incised	Royal dedicatory stela; provenance unknown; pre-1836	CIS, vol. 2.1, 143 = *RÉS* 490	B.3.f.17

TABLES 14-15. *Chronological List of the Discovery of Ostraca and Jar Inscriptions*

TABLE 14. *Ostraca.* Thirty-four separate finds or acquisitions between 1875 and 1988

	Dates	Item	Site	Discoverer/Acquirer	Museum/Library	Editio Princeps	Fitzmyer-Kaufman
1.	1875 (1889)	Fragmentary letter	Elephantine	Greville Chester	British Museum, London	CIS, vol. 2.1, 138	B.3.c.28
2.	1876 (1889)	Fragmentary letter	Elephantine	Chester	London	CIS, vol. 2.1, 139	B.3.c.48 APE 95
3.	pre-1880 (1915)	2 fragmentary letters	Elephantine	Friedrich Mook	Staatliche Sammlung Ägyptische Kunst, Munich	Mark Lidzbarski	B.3.c.24-25
4.	1886 (1887)	Dream letter	Elephantine	Adolf Erman	Staatliche Museen, Berlin	Julius Euting	B.3.c.47
5.	1888-1889 (1889)	2 lists	Elephantine	Vladimir S. Golénischeff	Pushkin Museum, Moscow	CIS, vol. 2.1, 154-155	B.3.c.39-40
6.	1897 (1906)	Fragmentary letter	Elephantine	Ludwig Borchardt	Berlin	Archibald Henry Sayce, Arthur Ernest Cowley	B.3.c.42/48 APO 77/1
7.	1897	Unknown	Oxyrhynchus		Columbia University	Unpublished	
8.	1900-1901 (1903)	4 letters	Elephantine	Sayce	Bodleian Library, Oxford (on permanent loan to the Ashmolean Museum, Oxford)	Cowley	B.3.c.29, 36-37, 48 APE 93
9.	1902 (1909, 1915)	2 letters (barley, *marzeah*), 1 fragmentary list	Elephantine		Egyptian Museum, Cairo	Sayce, Lidzbarski	B.3.c.33-32
10.	1905 (1911)	2 letters	Elephantine	Otto Rubensohn	Berlin	Eduard Sachau	B.3.c.21, 23
11.	1905-1906 (1911)	1 fragmentary letter; 3 accounts	Edfu	Carl Schmidt	Berlin	Sachau	B3.f.33.1-4
12.	1906 (1969)	1 fragmentary letter	Elephantine?		London	Judah Benzion Segal	B3.c.35
13.	1906 (1991)	1 letter; 1 list	Elephantine?	Rustafjaell sale at Sotheby's auction	London	Bezalel Porten, Ada Yardeni	
14.	1906-1908 (1911)	23 ostraca	Elephantine	Rubensohn, Friedrich Zucker	Berlin; Cairo	Sachau	B3.c.22, 41, 43, 48
15.	Unknown	1 list; 6 letters	Elephantine	Unknown	Berlin	Unpublished	
16.	1907-1909 (1944, 1945, 1948, 1949, 1957, 1963, 1971, 1989)	256? ostraca	Elephantine	Charles Clermont-Ganneau, Jean Clédat, Henri Gauthier	Académie des Inscriptions et Belles-Lettres, Paris	André Dupont-Sommer, Hélène Lozachmeur	B.3.c.33
17.	pre-1908 (1915)	2 accounts; 1 letter	Edfu?		Bibliothèque Nationale et Universitaire, Strasbourg	Lidzbarski	B.3.c.44-46

TABLE 14. *Ostraca (Continued)*

	Dates	Item	Site	Discoverer/Acquirer	Museum/Library	Editio Princeps	Fitzmyer-Kaufman
18.	pre-1911 (1911)	Passover letter	Elephantine	Sayce	Bodleian Library, Oxford (on permanent loan to the Ashmolean Museum, Oxford)	Sayce	B.3.c.20
19.	1911 (1978)	2 accounts; 2 letters	3 Edfu?; 1 Elephantine	Hermann Junker	Österreichische Nationalbibliothek, Vienna	Rainer Degen	B.3.c.19f.40
20.	1912 (1913)	Account	Kom el-Ahmar	Raymond Weil	Louvre	Raymond Weill	
21.	1914	Fragmentary letter	Unknown	Sayce	Bodleian Library, Oxford (on permanent loan to the Ashmolean Museum, Oxford)	Unpublished	
22.	1924 (1926)	Fragmentary letter	Elephantine		Cairo	Noel Aimé-Giron	B.3.c.27
23.	1925 (1926)	Tunic letter	Elephantine		Cairo	Aimé-Giron	B.3.c.28

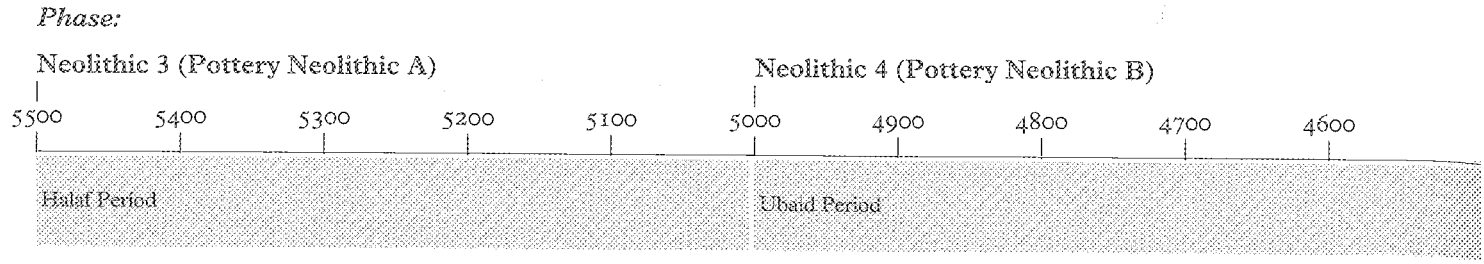
TABLE 15. *Jar Inscriptions.* Nine separate finds or acquisitions between 1906 and 1979

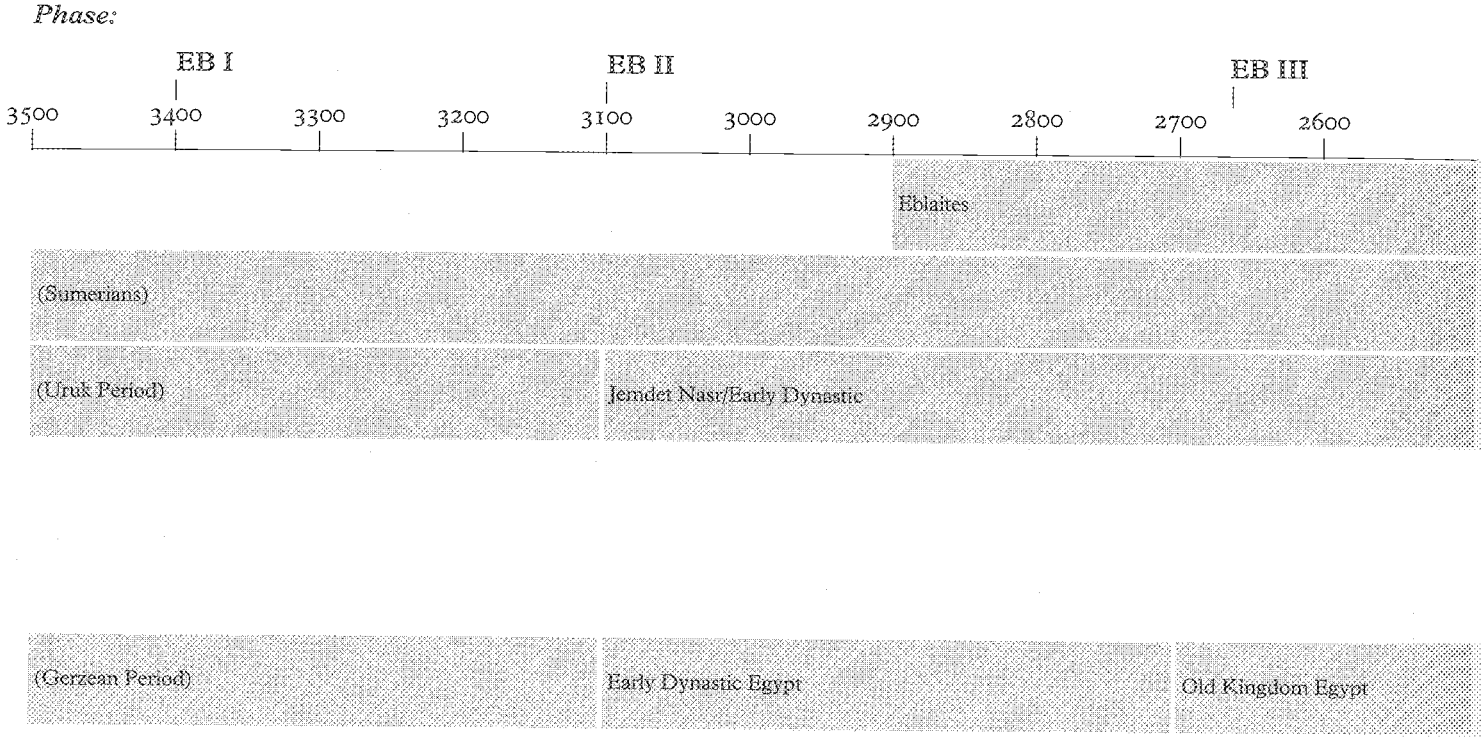
1.	1906-1908 (1911)	14 jar inscriptions	Elephantine	Otto Rubensohn	Staatliche Museen, Berlin; Egyptian Museum, Cairo	Eduard Sachau	B.3.c.49
2.	Unknown	1 jar inscription	Elephantine	Unknown	Berlin	Unpublished	
3.	1907 (1911)	2 jar inscriptions	Abu Sir (Memphis)	Ludwig Borchardt	Berlin	Sachau	
4.	1911 (1931)	1 jar inscription	Saqqara	Unknown	Cairo	Noel Aimé-Giron	B.3.c.1
4a.	Unknown (1939)	Potter's mark	South Saqqara	Cecil Mallaby Firth	Cairo	Aimé-Giron	Omitted (not Aramaic)
5.	1978-1979	Potter's mark	Saqqara	Edda Bresciani		Bresciani	B.3.f.9
6.	1929 (1931)	1 jar inscription	Edfu	Pierre Lacau	Cairo	Aimé-Giron	B.3.f.33.5
7.	1966-1973	2 jar inscriptions; 2 potter's marks	North Saqqara	Egypt Exploration Society	Saqqara Storeroom	Judah Benzion Segal	B.3.e.25
8.	pre-1987	2 jar inscriptions	Elephantine	German Archaeological Institute	Elephantine Storeroom	Mohammed Maraqten	
9.	1979	2 jar inscriptions	Elephantine	German Archaeological Institute	Elephantine Storeroom	Maraqten	

APPENDIX 2: CHRONOLOGIES

The table below provides a general chronology based on material culture and, for the later periods, historical events. The dates listed do not necessarily apply in all regions. For further discussion of dating, see "Periodization" and the survey articles on major regions (e.g., "Egypt," "Mesopotamia," "Palestine").

Phase	*Variants*	*Dates*
Upper Paleolithic		c. 43,000–18,000 BCE
Epipaleolithic	Mesolithic	18,000–8,500
Neolithic 1	Pre-Pottery Neolithic A	8500–7200
Neolithic 2	Pre-Pottery Neolithic B	7200–6000
Neolithic 3	Pottery Neolithic A	6000–5000
Neolithic 4	Pottery Neolithic B	5000–4500
Early Chalcolithic		4500–3800
Late Chalcolithic	Proto-Urban	3800–3400
Early Bronze IA-B		3400–3100
Early Bronze II		3100–2650
Early Bronze III		2650–2300
Early Bronze IVA-C	Intermediate Early–Middle Bronze, Middle Bronze I	2300–2000
Middle Bronze I	Middle Bronze IIA	2000–1800
Middle Bronze II	Middle Bronze IIB	1800–1650
Middle Bronze III	Middle Bronze IIC	1650–1500
Late Bronze IA		1500–1450
Late Bronze IB		1450–1400
Late Bronze IIA		1400–1300
Late Bronze IIB		1300–1200
Iron IA		1200–1125
Iron IB		1125–1000
Iron IC	Iron IIA	1000–925
Iron IIA	Iron IIB	925–722
Iron IIB	Iron IIC	722–586
Iron III	Neo-Babylonian	586–520
Early Persian		520–450
Late Persian		450–332
Early Hellenistic		332–200
Late Hellenistic		200–63
Early Roman		63 BCE–135 CE
Middle Roman		135–250
Late Roman		250–363
Early Byzantine		363–460
Late Byzantine		460–638
Early Arab		638–1099
Crusader and Ayyubid		1099–1291
Late Arab		1291–1516
Ottoman		1516–1917





This time line is intended as a general guide for the non-specialist reader to show the approximate span of major cultures and periods and their contemporaneity with other Near Eastern cultures and periods. Related items tend to be placed near each other, and to the extent possible, succeeding dynasties or periods within a single culture follow along the same line; this is not intended to imply, however, that items on the same line are necessarily related.

APPENDIX 3: MAPS

The maps that appear on the following pages are primarily intended to show the locations of the sites and regions covered in this encyclopedia. Sites that are the subject of independent entries are marked with solid dots; other important sites are marked with open circles.

1. Palestine and Transjordan
2. Northern Palestine and Transjordan (detail of map 1)
3. Southern Palestine and Transjordan (detail of map 1)
4. Syria
5. Anatolia
6. Armenia
7. Mesopotamia and Persia
8. Lower Egypt
9. Northeast Africa and South Arabia
10. Arabian Peninsula
11. North Africa and the Aegean Islands
12. Cyprus

The area of each map is indicated on the general map of the Near East on the following page.

DIRECTORY OF CONTRIBUTORS

Abadie-Reynal, Catherine
Scientific Secretary, Institut Français d'Études Anatoliennes
Institut Français d'Études Anatoliennes d'Istanbul

Abou Assaf, Ali
Professor Emeritus of Archaeology and West Semitic Languages, Damascus, Syria
'Ain Dara'; Fakhariyah, Tell; Homs; Mishrifeh; Rifa'at, Tell; Sukas, Tell; Syria, *article on* Syria in the Iron Age

Abusch, Tzvi
Cohen Professor of Assyriology and Ancient Near Eastern Religion, Brandeis University
Jacobsen, Thorkild

Adan-Bayewitz, David
Senior Lecturer in Archaeology, Bar-Ilan University
Kefar Hananyah

Aitken, Martin J.
Professor Emeritus of Archaeometry, University of Oxford
Dating Techniques

Allen, James P.
Associate Curator of Egyptian Art, The Metropolitan Museum of Art, New York
Heliopolis

Allen, Susan J.
Research Associate, Department of Egyptian Art, The Metropolitan Museum of Art, New York
Institut Français d'Archéologie Orientale (Cairo)

Alpert Nakhai, Beth
Lecturer in Judaic Studies and Near Eastern Studies, University of Arizona
Beth-Zur; Furniture and Furnishings, *article on* Furnishings of the Bronze and Iron Ages; Kitan, Tel; Locus; Temples, *article on* Syro-Palestinian Temples; Wawiyat, Tell el-

Amadasi Guzzo, Maria Giulia
Professor of Semitic Epigraphy, Università di Roma "La Sapienza"
Levi Della Vida, Giorgio; Phoenician-Punic

Amiran, Ruth
Field Archaeologist (retired), The Israel Museum
Arad, *article on* Bronze Age Period

Amitai, Janet
Independent Scholar, Jerusalem, Israel
Israel Exploration Society

Anderson, J. K.
Professor Emeritus of Classical Archaeology, University of California, Berkeley
Hunting

Anderson-Stojanović, Virginia R.
Professor of Classics and Fine Arts, Wilson College
Leather

André-Salvini, Beatrice
Chief Curator, Département des Antiquités Orientales, Musée du Louvre, Paris
Thureau-Dangin, François

Ansary, Abdul Rahman T. al-
Professor of Pre-Islamic Archaeology and Epigraphy of the Arabian Peninsula, King Saud University
Arabian Peninsula, *article on* The Arabian Peninsula in Islamic Times; Qaryat al-Fau

Arav, Rami
Director, Bethsaida Excavations Project
Bethsaida

Archi, Alfonso
Professor of Hittitology, Università di Roma "La Sapienza"
Ebla Texts

Armstrong, James A.
Assistant Curator of Collections, Semitic Museum, Harvard University
Ceramics, *article on* Mesopotamian Ceramics of the Neolithic through Neo-Bablyonian Periods

Arnold, Dieter
Curator, Department of Egyptian Art, The Metropolitan Museum of Art, New York
Temples, *article on* Egyptian Temples

Arnold, Felix
Field Archaeologist and Independent Scholar, Karlsruhe, Germany
House, *article on* Egyptian Houses

Artzy, Michal
Professor of Archaeology and Maritime Civilizations, University of Haifa
Nami, Tel

Åström, Paul
Professor Emeritus of Ancient Culture and Civilization, Göteborg University
Hala Sultan Tekke

Aubin, Melissa M.
Doctoral candidate, Department of Religion, Duke University
Jerash

Auerbach, Elise
Postdoctoral Fellow in the History of Art and the Humanities, Getty Grant Program
Eshnunna

Auld, Graeme
Professor of Hebrew Bible, University of Edinburgh
British School of Archaeology in Jerusalem

Aune, David E.
Professor of New Testament and Christian Origins, Loyola University of Chicago
Amulets; Chalcedon; Greek; Latin

Avalos, Hector Ignacio
Assistant Professor of Religious Studies and Latino Studies, Iowa State University
Medicine

Aviam, Mordechai
Western Galilee District Archaeologist, Israel Antiquities Authority
Magdala; Tabgha; Tabor, Mount

Bacharach, Jere L.
Professor of History, University of Washington
Middle East Studies Association

Badre, Leila
Curator, American University of Beirut Museum
Arwad; Baalbek; Kamid el-Loz; Khaldeh; Shabwa

Bahat, Dan
Senior Lecturer in History and Archaeology of Jerusalem, Bar-Ilan University
Jerusalem

Balty, Jean Ch.
Professor of Classical Archaeology, Université Libre de Bruxelles; and Head, Department of Antiquities, Musées Royaux d'Art et d'Histoire, Brussels
Apamea; Odeum

Bammer, Anton
University Docent for Ancient Architecture and Archaeology, University of Vienna
Ephesus

Banning, E. B.
Professor of Archaeology, University of Toronto
Ziqlab, Wadi

Barag, Dan
Professor of Archaeology, Institute of Archaeology, Hebrew University of Jerusalem
Marquet-Krause, Judith

Barber, E. J. W.
Professor of Archaeology and Linguistics, Occidental College
Textiles, *article on* Textiles of the Neolithic through Iron Ages

Bar-Ilan, Meir
Professor of Jewish History and Talmud, Bar-Ilan University
Papyrus; Parchment

Bartlett, John R.
Principal, Church of Ireland Theological College, Dublin
Edom

Bar-Yosef, Ofer
McCurdy Professor of Prehistoric Archaeology, Peabody Museum, Harvard University

Worschech, Udo
Professor of Old Testament Studies, Theologisches Hochschule Friedensau
Balu'

Wright, G. R. H.
Consultant in Monument Restoration; and Research Associate, Archaeological Center, Universiteit Leiden
Building Materials and Techniques, *articles on* Materials and Techniques of the Bronze and Iron Ages *and* Materials and Techniques of the Persian through Roman Periods; Restoration and Conservation

Wright, Henry T., III
Curator of Archaeology, Museum of Anthropology, and Professor of Anthropology, University of Michigan
Tepe Farukhabad

Wright, J. Edward
Assistant Professor of Near Eastern and Judaic Studies, University of Arizona
Judean Desert Caves

Wright, Katherine I.
Lecturer in Archaeology, Institute of Archeology, University College London
Shu'eib, Wadi

Wright, Robert B.
Professor of Hebrew Bible and Post-Biblical Literature, Temple University
Photography, *article on* Photography of Fieldwork and Artifacts

Xella, Paolo
Researcher in Chief, C.N.R. Istituto perla Civiltà Fenicia e Punica, Rome; and Adjunct Professor of Oriental Studies, Eberhard-Karls-Universität Tübingen
Marseille Tariff

Yakar, Jak
Professor of Anatolian Archaeology and Ancient Near Eastern Cultures, Tel Aviv University
Hacılar; History of the Field, *article on* Archaeology in the Anatolian Plateau; Koşay, Hamit Zübeyr

Yassine, Khair
Chairman, Department of History and Archaeology, United Arab Emirates University
Mazar, Tell el-

Yellin, Joseph
Associate Professor of Archaeometry and Physics, Hebrew University of Jerusalem
Neutron Activation Analysis

Yener, K. Aslıhan
Assistant Professor of Anatolian Archaeology, The Oriental Institute, University of Chicago
Göltepe; Kestel; Taurus Mountains

Yon, Marguerite
Professor and Directeur de Recherche in Oriental Archaeology, Maison de l'Orient (Université Lumière Lyon 2-CNRS)
French Archaeological Missions; Kition; Stelae; Ugarit

Young, T. Cuyler, Jr.
Curator, West Asian Department, Royal Ontario Museum
Godin Tepe; Medes; Persians

Zadok, Ran
Professor of Mesopotamian, Iranian, and Judaic Studies, Tel Aviv University
Names and Naming

Zarins, Juris
Professor of Anthropology, Southwest Missouri State University
Euphrates; Najran; Oman; Sohar; Ubar

Zayadine, Fawzi
Deputy Director, Department of Antiquities, Jordan
'Iraq el-Amir

Zeder, Melinda A.
Associate Curator of Archaeology, National Museum of Natural History, Smithsonian Institution
Sheep and Goats

Zertal, Adam
Professor of Archaeology, University of Haifa
Ebal, Mount; Northern Samaria, Survey of

Zettler, Richard L.
Associate Professor of Anthropology, University of Pennsylvania
Eridu; Hilprecht, Hermann Vollrat; Nippur; Peters, John Punnett

Zevit, Ziony
Professor of Biblical Literature and Northwest Semitic Languages and Literatures, University of Judaism
Greenfield, Jonas Carl

Zias, Joseph
Curator of Anthropology and Archaeology, Israel Antiquities Authority
Paleopathology

Zimansky, Paul E.
Associate Professor of Archaeology, Boston University
Urartu

Zimmerman, Larry J.
Distinguished Regents Professor of Anthropology, University of South Dakota
Ethics and Archaeology

Zivie-Coche, Cristiane
Directeur d'Études, Religion de l'Egypte Ancienne, École Pratique des Hautes Études, Section des Sciences Religieuses, Paris
Giza

Zorn, Jeffrey R.
Independent scholar, San Jacinto, California
Badè, William Frederic; Naṣbeh, Tell en-

Zournatzi, Antigoni
Associate Senior Lecturer in Classical Archaeology, Institut d'Archéologie et d'Histoire Anciennes, Maison de l'Orient Méditerraneen et Université Lumière Lyon-2

Zuckerman, Bruce
Associate Professor of Religion, University of Southern California
Photography, *article on* Photography of Manuscripts

Zuckerman, Kenneth
Partner, West Semitic Research, California
Photography, *article on* Photography of Manuscripts

SYNOPTIC OUTLINE OF CONTENTS

The outline presented on the following pages is intended to provide a general view of the conceptual scheme of this encyclopedia. Entries are arranged in the conceptual categories listed below. Because the headings for these categories are not necessarily mutually exclusive, some entries in the encyclopedia are listed more than once.

Lands and Peoples
- Syria-Palestine
- Mesopotamia
- Anatolia
- Cyprus and the Aegean
- Persia
- Arabian Peninsula
- Egypt
- North Africa
- Semitic East Africa
- Major Empires

Writing, Language, Texts
- Language Families and Languages
- Inscriptions and Texts
- Writing and Literacy
- Writing Materials and Technologies

Material Culture
- Subsistence, Trade, and Society
- Built Structures
- Artifacts and Technologies

Archaeological Methods
- Types of Archaeology
- Site Typology
- Artifact Analysis
- Dating Techniques
- Provenience Studies
- Field Methods
- Allied Sciences and Disciplines

History of Archaeology
- Theory and Practice
- Narrative Histories
- Organizations and Institutions
- Biographies

LANDS AND PEOPLES

Syria-Palestine

Overviews

Palestine
- Prehistoric Palestine
- Palestine in the Bronze Age
- Palestine in the Iron Age
- Palestine in the Persian through Roman Periods
- Palestine in the Byzantine Period
- Palestine in the Islamic Period

Phoenicia

Syria
- Prehistoric Syria
- Syria in the Bronze Age
- Syria in the Iron Age
- Syria in the Persian through Roman Periods
- Syria in the Byzantine Period
- Syria in the Islamic Period

Transjordan
- Prehistoric Transjordan
- Transjordan in the Bronze and Iron Ages
- Transjordan in the Persian through Roman Periods
- Transjordan in the Byzantine Period
- Transjordan in the Islamic Period

Regional Definitions

Coele-Syria
Levant
Syria-Palestine

Peoples, Polities, and Events

Ammon
Arameans
Bar Kokhba Revolt
Canaan
Canaanites
Central Moab
Eblaites
Edom
Essenes
First Jewish Revolt
Gilead
Hasmoneans
Idumeans
Israelites
Mitanni
Moab
Nabateans
Neo-Hittites
Philistines
- Early Philistines
- Late Philistines

Phoenicians
Samaritans

Subregions and Sites in Palestine

Abu Hawam, Tell
Achziv
Ai
ʿAin es-Samiyeh
ʿAjjul, Tell el-
